Last time: Summary

- Definition of AI?
- Turing Test?
- Intelligent Agents:
 - Anything that can be viewed as perceiving its environment through sensors and acting upon that environment through its effectors to maximize progress towards its goals.
 - PAGE (Percepts, Actions, Goals, Environment)
 - Described as a Perception (sequence) to Action Mapping: $f: \mathcal{P}^* \to \mathcal{A}$
 - Using look-up-table, closed form, etc.
- **Agent Types:** Reflex, state-based, goal-based, utility-based
- **Rational Action:** The action that maximizes the expected value of the performance measure given the percept sequence to date

Outline: Problem solving and search

- Introduction to Problem Solving
- Complexity

• Uninformed search

- Problem formulation
- Search strategies: depth-first, breadth-first

• Informed search

- Search strategies: best-first, A*
- Heuristic functions

• **Problem:** Using these three buckets, measure 7 liters of water.

Which solution do we prefer?

Problem-Solving Agent

```
function SIMPLE-PROBLEM-SOLVING-AGENT(p) returns an action
   inputs: p, a percept
   static: s, an action sequence, initially empty
            state, some description of the current world state
            q, a goal, initially null
            problem, a problem formulation
   state \leftarrow UPDATE-STATE(state, p)
   if s is empty then
        g \leftarrow \text{FORMULATE-GOAL}(state)
        problem \leftarrow FORMULATE-PROBLEM(state, g)
        s \leftarrow \text{SEARCH}(problem)
   action \leftarrow \text{Recommendation}(s, state)
   s \leftarrow \text{REMAINDER}(s, state)
   return action
```

Note: This is *offline* problem-solving. *Online* problem-solving involves acting w/o complete knowledge of the problem and environment

Example: Buckets

- Measure 7 liters of water using a 3 liter, a 5 liter, and a 9 liter bucket.
- Formulate goal: Have 7 liters of water in 9-liter bucket
- Formulate problem:
 - States: amount of water in the buckets
 - Operators: Fill bucket from source, empty bucket
- Find solution: sequence of operators that bring you from current state to the goal state

Remember (lecture 2): Environment types

| Environment | Accessible | Deterministic | Episodic | Static | Discrete |
|-----------------------|------------|---------------|----------|--------|----------|
| Operating System | Yes | Yes | No | No | Yes |
| Virtual Reality | Yes | Yes | Yes/No | No | Yes/No |
| Office Environment | No | No | No | No | No |
| Mars | No | Semi | No | Semi | No |

The environment types largely determine the agent design.

Problem types

- **Single-state problem:** deterministic, accessible Agent knows everything about world, thus can calculate optimal action sequence to reach goal state.
- **Multiple-state problem:** deterministic, inaccessible

Agent must reason about sequences of actions and states assumed while working towards goal state.

- **Contingency problem:** nondeterministic, inaccessible
 - Must use sensors during execution
 - Solution is a tree or policy
 - Often interleave search and execution
- **Exploration problem:** unknown state space

Discover and learn about environment while taking actions. CS 561. Lectures 3-5

Example: Vacuum world

Simplified world: 2 locations, each may or not contain dirt, each may or not contain vacuuming agent. Goal of agent: clean up the dirt.

Single-state, start in #5. <u>Solution</u>??

<u>Multiple-state</u>, start in $\{1, 2, 3, 4, 5, 6, 7, 8\}$ e.g., *Right* goes to $\{2, 4, 6, 8\}$. <u>Solution</u>??

<u>Contingency</u>, start in #5 Murphy's Law: *Suck* can dirty a clean carpet Local sensing: dirt, location only. <u>Solution</u>??

Example: Romania

- In Romania, on vacation. Currently in Arad.
- Flight leaves tomorrow from Bucharest.
- Formulate goal:
- ➢ be in Bucharest
- Formulate problem:
- states: various cities
- > operators: drive between cities
- Find solution:
- > sequence of cities, such that total driving distance is minimized.

Example: Traveling from Arad To Bucharest

CS 561, Lectures 3-5

Problem formulation

A *problem* is defined by four items:

initial state e.g., "at Arad"

 $\frac{operators}{e.g., Arad} \rightarrow \text{Zerind} \qquad Arad \rightarrow \text{Sibiu} \qquad \text{etc.}$

 $\underline{goal \ test}$, can be explicit, e.g., x = "at Bucharest" implicit, e.g., NoDirt(x)

<u>path</u> cost (additive)

e.g., sum of distances, number of operators executed, etc.

A *solution* is a sequence of operators leading from the initial state to a goal state

Selecting a state space

- Real world is absurdly complex; some abstraction is necessary to allow us to reason on it...
- Selecting the correct abstraction and resulting state space is a difficult problem!
- Abstract states \Leftrightarrow real-world states
- Abstract operators (e.g., going from city i to city j costs Lij actually drive from city i to j)

Example: 8-puzzle

- State:
- Operators:
- Goal test:
- Path cost:

Example: 8-puzzle

- State: integer location of tiles (ignore intermediate locations)
- Operators: moving blank left, right, up, down (ignore jamming)
- Goal test: does state match goal state?
- Path cost: 1 per move

Example: 8-puzzle

- Why search algorithms?
 - 8-puzzle has 362,800 states
 - 15-puzzle has 10^12 states
 - 24-puzzle has 10^25 states

So, we need a principled way to look for a solution in these huge search spaces...

Back to Vacuum World

<u>states</u>?? operators?? <u>goal test</u>?? path cost??

CS 561, Lectures 3-5

Back to Vacuum World

<u>states</u>??: integer dirt and robot locations (ignore dirt *amounts*) <u>operators</u>??: Left, Right, Suck <u>goal test</u>??: no dirt <u>path cost</u>??: 1 per operator

Example: Robotic Assembly

<u>states</u>??: real-valued coordinates of robot joint angles parts of the object to be assembled

operators ??: continuous motions of robot joints

goal test??: complete assembly with no robot included!

path cost??: time to execute

CS 561, Lectures 3-5

Real-life example: VLSI Layout

- Given schematic diagram comprising components (chips, resistors, capacitors, etc) and interconnections (wires), find optimal way to place components on a printed circuit board, under the constraint that only a small number of wire layers are available (and wires on a given layer cannot cross!)
- "optimal way"??
- minimize surface area
- minimize number of signal layers
- minimize number of vias (connections from one layer to another)
- minimize length of some signal lines (e.g., clock line)
- distribute heat throughout board
- ≻ etc.

Protel's hierarchical schematic design features let you take a "bottom up" or "top down" approach, depending on your preferred methodology. Protel can automatically generate sub-sheets based on higher-level sheet symbols, or create sheet symbols based on existing sheets. 36

Enter schematics;

Protel 99 SE's unique 3D visualization feature lets you see your finished board before it leaves your desktop. Sophisticated 3D modeling and extrusion techniques render your board in stunning 3D without the need for additional height information. Rotate and zoom to examine every aspect of your board. 38

CS 561, Lectures 3-5

Search algorithms

Basic idea:

offline, systematic exploration of simulated state-space by generating successors of explored states (expanding)

Function General-Search(*problem, strategy*) returns a *solution*, or failure initialize the search tree using the initial state problem

 loop do
 if there are no candidates for expansion then return failure choose a leaf node for expansion according to strategy

 if the node contains a goal state then return the corresponding solution else expand the node and add resulting nodes to the search tree

 end

CS 561, Lectures 3-5

From problem space to search tree

 Some material in this and following slides is from <u>http://www.cs.kuleuven.ac.be/~dannyd/FAI/</u> check it out!

Problem space

Associated loop-free search tree

Paths in search trees

Implementation of search algorithms

Function General-Search(problem, Queuing-Fn) returns a solution, or failure
nodes ← make-queue(make-node(initial-state[problem]))
loop do
if nodes is empty then return failure
node ← Remove-Front(nodes)
if Goal-Test[problem] applied to State(node) succeeds then return node
nodes ← Queuing-Fn(nodes, Expand(node, Operators[problem]))
end

Queuing-Fn(*queue, elements***)** is a queuing function that inserts a set of elements into the queue and <u>determines the order of node expansion</u>. Varieties of the queuing function produce varieties of the search algorithm.

Encapsulating *state* information in *nodes*

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x)States do not have parents, children, depth, or path cost! parent State 54618732state g=6children

The EXPAND function creates new nodes, filling in the various fields and using the OPERATORS (or SUCCESSORFN) of the problem to create the corresponding states.

Evaluation of search strategies

- A search strategy is defined by picking the order of node expansion.
- Search algorithms are commonly evaluated according to the following four criteria:
 - **Completeness:** does it always find a solution if one exists?
 - **Time complexity:** how long does it take as function of num. of nodes?
 - **Space complexity:** how much memory does it require?
 - **Optimality:** does it guarantee the least-cost solution?
- Time and space complexity are measured in terms of:
 - $b \max$ branching factor of the search tree
 - d depth of the least-cost solution
 - *m* max depth of the search tree (may be infinity)

Complexity

- Why worry about complexity of algorithms?
- because a problem may be solvable in principle but may take too long to solve in practice

- How can we evaluate the complexity of algorithms?
- through asymptotic analysis, i.e., estimate time (or number of operations) necessary to solve an instance of size *n* of a problem when *n* tends towards infinity
- ➢ See AIMA, Appendix A.

Complexity example: Traveling Salesman Problem

- There are n cities, with a road of length L_{ij} joining city i to city j.
- The salesman wishes to find a way to visit all cities that is optimal in two ways: each city is visited only once, and the total route is as short as possible.

• This is a *hard* problem: the only known algorithms (so far) to solve it have exponential complexity, that is, the number of operations required to solve it grows as *exp(n)* for *n* cities.

CS 561, Lectures 3-5

Why is exponential complexity "hard"?

It means that the number of operations necessary to compute the exact solution of the problem grows exponentially with the size of the problem (here, the number of cities).

- exp(1) = 2.72
- $exp(10) = 2.20 \ 10^4$ (daily salesman trip)
- $exp(100) = 2.69 \ 10^{43}$ (monthly salesman planning)
- exp(500) = 1.40 10²¹⁷ (music band worldwide tour)
 - $exp(250,000) = 10^{108,573}$ (fedex, postal services)
- Fastest computer $= 10^{12}$ operations/second

So...

In general, exponential-complexity problems *cannot be solved for any but the smallest instances!*

Complexity

- Polynomial-time (P) problems: we can find algorithms that will solve them in a time (=number of operations) that grows polynomially with the size of the input.
- for example: sort n numbers into increasing order: poor algorithms have n^2 complexity, better ones have n log(n) complexity.
- Since we did not state what the order of the polynomial is, it could be very large! Are there algorithms that require more than polynomial time?
- Yes (until proof of the contrary); for some algorithms, we do not know of any polynomial-time algorithm to solve them. These are referred to as nondeterministic-polynomial-time (NP) algorithms.
- ➢ for example: traveling salesman problem.
- In particular, exponential-time algorithms are believed to be NP.

Note on NP-hard problems

• The formal definition of NP problems is:

A problem is nondeterministic polynomial if there exists some algorithm that can guess a solution and then verify whether or not the guess is correct in polynomial time.

(one can also state this as these problems being solvable in polynomial time on a nondeterministic Turing machine.)

In practice, until proof of the contrary, this means that known algorithms that run on known computer architectures will take more than polynomial time to solve the problem.

Complexity: O() and o() measures (Landau symbols)

- How can we represent the complexity of an algorithm?
- Given: Problem input (or instance) size: n
 Number of operations to solve problem: f(n)
- If, for a given function g(n), we have:

 $\exists k \in \Re, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N}, n \ge n_0, f(n) \le kg(n)$ then $f \in O(g)$ f is dominated by g

• If, for a given function g(n), we have:

 $\forall k \in \mathfrak{R}, \exists n_0 \in \mathbb{N}, \forall n \in \mathbb{N}, n \ge n_0, f(n) \le kg(n)$

then $f \in o(g)$ f is negligible compared to g CS 561, Lectures 3-5

Landau symbols

$$f \in O(g) \Leftrightarrow \exists k, f(n) \leq kg(n) \Leftrightarrow \frac{f}{g}$$
 is bounded

$$f \in o(g) \Leftrightarrow \forall k, f(n) \underset{n \to \infty}{\leq} kg(n) \Leftrightarrow \frac{f(n)}{g(n)} \underset{n \to \infty}{\longrightarrow} 0$$

Examples, properties

- f(n)=n, g(n)=n^2:

 n is o(n^2), because n/n^2 = 1/n -> 0 as n ->infinity similarly,
 log(n) is o(n)
 n^C is o(exp(n)) for any C
- if f is O(g), then for any K, K.f is also O(g); idem for o()
- if f is O(h) and g is O(h), then for any K, L: K.f + L.g is O(h) idem for o()
- if f is O(g) and g is O(h), then f is O(h)
- if f is O(g) and g is o(h), then f is o(h)
- if f is o(g) and g is O(h), then f is o(h)

Polynomial-time hierarchy

Complexity and the human brain

- Are computers close to human brain power?
- Current computer chip (CPU):
 - 10³ inputs (pins)
 - 10^7 processing elements (gates)
 - 2 inputs per processing element (fan-in = 2)
 - processing elements compute boolean logic (OR, AND, NOT, etc)
- Typical human brain:
 - 10^7 inputs (sensors)
 - 10^10 processing elements (neurons)
 - fan-in = 10^3
 - processing elements compute complicated functions

intel pentum o unel os

CS 561, Lectures 3-5

Remember: Implementation of search algorithms

Function General-Search(problem, Queuing-Fn) returns a solution, or failure
nodes ← make-queue(make-node(initial-state[problem]))
loop do
 if nodes is empty then return failure
 node ← Remove-Front(nodes)
 if Goal-Test[problem] applied to State(node) succeeds then return node
 nodes ← Queuing-Fn(nodes, Expand(node, Operators[problem]))
end

Queuing-Fn(*queue, elements***)** is a queuing function that inserts a set of elements into the queue and <u>determines the order of node expansion</u>. Varieties of the queuing function produce varieties of the search algorithm.

Encapsulating *state* information in *nodes*

A state is a (representation of) a physical configuration A node is a data structure constituting part of a search tree includes parent, children, depth, path cost g(x)States do not have parents, children, depth, or path cost! parent State 54618732state g=6children

The EXPAND function creates new nodes, filling in the various fields and using the OPERATORS (or SUCCESSORFN) of the problem to create the corresponding states.

Evaluation of search strategies

- A search strategy is defined by picking the order of node expansion.
- Search algorithms are commonly evaluated according to the following four criteria:
 - **Completeness:** does it always find a solution if one exists?
 - **Time complexity:** how long does it take as function of num. of nodes?
 - **Space complexity:** how much memory does it require?
 - **Optimality:** does it guarantee the least-cost solution?
- Time and space complexity are measured in terms of:
 - $b \max$ branching factor of the search tree
 - d depth of the least-cost solution
 - *m* max depth of the search tree (may be infinity)

Note: Approximations

- In our complexity analysis, we do not take the built-in <u>loop-</u> <u>detection</u> into account.
- The results only 'formally' apply to the variants of our algorithms WITHOUT loop-checks.
- Studying the effect of the loop-checking on the complexity is hard:
 - overhead of the checking MAY or MAY NOT be compensated by the reduction of the size of the tree.
- <u>Also</u>: our analysis <u>DOES NOT</u> take the length (space) of representing paths into account !!

http://www.cs.kuleuven.ac.be/~dannyd/FAI/

CS 561, Lectures 3-5

Uninformed search strategies

Use only information available in the problem formulation

- Breadth-first
- Uniform-cost
- Depth-first
- Depth-limited
- Iterative deepening
Breadth-first search

Expand shallowest unexpanded node

Implementation:

$\operatorname{QUEUEINGFN}$ = put successors at end of queue

Example: Traveling from Arad To Bucharest

CS 561, Lectures 3-5

Breadth-first search

Breadth-first search

Properties of breadth-first search

- Completeness:
- Time complexity:
- Space complexity:
- Optimality:
- Search algorithms are commonly evaluated according to the following four criteria:
 - **Completeness:** does it always find a solution if one exists?
 - **Time complexity:** how long does it take as function of num. of nodes?
 - **Space complexity:** how much memory does it require?
 - **Optimality:** does it guarantee the least-cost solution?
- Time and space complexity are measured in terms of:
 - *b* max branching factor of the search tree
 - *d* depth of the least-cost solution
 - *m* max depth of the search tree (may be infinity)

Properties of breadth-first search

- Completeness: Yes, if *b* is finite
- Time complexity:
- Space complexity:
- Optimality:

 $1+b+b^2+...+b^d = O(b^d)$, i.e., exponential in d $O(b^d)$, keeps every node in memory

Yes (assuming cost = 1 per step)

Why keep every node in memory? To avoid revisiting already-visited nodes, which may easily yield infinite loops.

Time complexity of breadth-first search

• If a goal node is found on depth d of the tree, all nodes up till that depth are created.

• <u>Thus</u>: O(b^d)

Space complexity of breadth-first

• Largest number of nodes in QUEUE is reached on the level d of the goal node.

Uniform-cost search

Expand least-cost unexpanded node

Implementation:

QUEUEINGFN = insert in order of increasing path cost

Arad

A refinement of the breadth-first strategy:

Breadth-first = uniform-cost with path cost = node depth

CS 561, Lectures 3-5

Romania with step costs in km

CS 561, Lectures 3-5

Uniform-cost search

Uniform-cost search

Properties of uniform-cost search

- Completeness: Yes, if step $cost \ge \varepsilon > 0$
- Time complexity:
- Space complexity:
- Optimality:

- # nodes with $g \le cost$ of optimal solution, $\le O(b^d)$
- # nodes with $g \leq cost$ of optimal solution, $\leq O(b^d)$
- Yes, as long as path cost never decreases

g(n) is the path cost to node n Remember:

- b = branching factor
- d = depth of least-cost solution

Implementation of uniform-cost search

- Initialize Queue with root node (built from start state)
- Repeat until (Queue is empty) or (first node has Goal state):
 - Remove first node from front of Queue
 - Expand node (find its children)
 - Reject those children that have already been considered, to avoid loops
 - Add remaining children to Queue, *in a way that keeps entire queue* sorted by increasing path cost
- If Goal was reached, return success, otherwise failure

Caution!

• Uniform-cost search not optimal if it is terminated when *any* node in the queue has goal state.

 Uniform cost returns the path with cost 102 (if any goal node is considered a solution), while there is a path with cost 25.

Note: Loop Detection

- In class, we saw that the search may fail or be sub-optimal if:
 - no loop detection: then algorithm runs into infinite cycles (A -> B -> A -> B -> ...)
 - not queueing-up a node that has a state which we have already visited: may yield suboptimal solution
 - simply avoiding to go back to our parent: looks promising, but we have not proven that it works
- Solution? do not enqueue a node if its state matches the state of any of its parents (assuming path costs>0).

Indeed, if path costs > 0, it will always cost us more to consider a
node with that state again than it had already cost us the first time.
Is that enough??

From: http://www.csee.umbc.edu/471/current/notes/uninformed-search/

Example Illustrating Uninformed Search Strategies

Breadth-First Search Solution

From: http://www.csee.umbc.edu/471/current/notes/uninformed-search/

Breadth-First Search

return GENERAL-SEARCH(problem, ENQUEUE-AT-END)

exp. node nodes list

```
{S}
S {ABC}
A {BCDEG}
B {CDEGG'}
C {DEGG'G"}
D {EGG'G"}
E {GG'G"}
G {G'G"}
```

Solution path found is SAG <--- this G also has cost 10 Number of nodes expanded (including goal node) = 7

Uniform-Cost Search Solution

From: http://www.csee.umbc.edu/471/current/notes/uninformed-search/

Uniform-Cost Search

GENERAL-SEARCH(problem, ENQUEUE-BY-PATH-COST)

exp. node nodes list

{ S }
S { A(1) B(5) C(8) }
A { D(4) B(5) C(8) E(8) G(10) } (NB, we don't return G)
D { B(5) C(8) E(8) G(10) }
B { C(8) E(8) G(9) G(10) }
C { E(8) G(9) G(10) G(13) }
E { G(9) G(10) G(13) }
G { }

Solution path found is SBG <-- this G has cost 9, not 10 Number of nodes expanded (including goal node) = 7

Note: Queueing in Uniform-Cost Search

- In the previous example, it is wasteful (but not incorrect) to queue-up three nodes with G state, if our goal if to find the least-cost solution:
- Although they represent different paths, we know for sure that the one with smallest path cost (9 in the example) will yield a solution with smaller total path cost than the others.

So we can refine the queueing function by:

- queue-up node if
 - 1) its state does not match the state of any parent
- and 2) path cost smaller than path cost of any unexpanded node with same state in the queue (and in this case, replace old node with same state by our new node)

Is that it??

A Clean Robust Algorithm

```
Function UniformCost-Search(problem, Queuing-Fn) returns a solution, or failure
   open ← make-queue(make-node(initial-state[problem]))
   closed \leftarrow [empty]
   loop do
         if open is empty then return failure
         currnode \leftarrow Remove-Front(open)
         if Goal-Test[problem] applied to State(currnode) then return currnode
         children ← Expand(currnode, Operators[problem])
         while children not empty
                           [... see next slide ...]
         end
         closed \leftarrow Insert(closed, currnode)
         open ← Sort-By-PathCost(open)
   end
```

A Clean Robust Algorithm

```
[... see previous slide ...]
         children \leftarrow Expand(currnode, Operators[problem])
         while children not empty
                   child \leftarrow Remove-Front(children)
                   if no node in open or closed has child's state
                             open \leftarrow Queuing-Fn(open, child)
                   else if there exists node in open that has child's state
                             if PathCost(child) < PathCost(node)
                                       open \leftarrow Delete-Node(open, node)
                                       open \leftarrow Queuing-Fn(open, child)
                   else if there exists node in closed that has child's state
                             if PathCost(child) < PathCost(node)
                                       closed ← Delete-Node(closed, node)
                                       open \leftarrow Queuing-Fn(open, child)
         end
```

Node 2 has 2 successors: one with state B and one with state S.

We have node #1 in *closed* with state S; but its path cost 0 is smaller than the path cost obtained by expanding from A to S. So we do not queue-up the successor of node 2 that has state S.

CS 561, Lectures 3-5

| # | State | Depth | Cost | Parent |
|---|-------|-------|------|--------|
| | 0 | 0 | 0 | |
| 1 | S | 0 | 0 | - |
| 2 | Α | 1 | 1 | 1 |
| 4 | В | 2 | 2 | 2 |
| 5 | С | 3 | 3 | 4 |
| 6 | G | 3 | 102 | 4 |

Node 4 has a successor with state C and Cost smaller than node #3 in *open* that Also had state C; so we update *open* To reflect the shortest path.

Depth-first search

Expand deepest unexpanded node

Implementation:

 $\operatorname{QUEUEINGFN}$ = insert successors at front of queue

Romania with step costs in km

CS 561, Lectures 3-5
Depth-first search

Depth-first search

Depth-first search

I.e., depth-first search can perform infinite cyclic excursions Need a finite, non-cyclic search space (or repeated-state checking) CS 561, Lectures 3-5 111

Properties of depth-first search

- Completeness: No, fails in infinite state-space (yes if finite state space)
- Time complexity: O(b^m)
- Space complexity: *O(bm)*
- Optimality: No

Remember:

b = branching factor

m = max depth of search tree

Time complexity of depth-first: details

• In the worst case:

•

• the (only) goal node may be on the right-most branch,

Space complexity of depth-first

- Largest number of nodes in QUEUE is reached in bottom leftmost node.
- Example: m = 3, b = 3 :

- QUEUE contains all en nodes. Thus: 7.
- In General: ((b-1) * m) + 1
- Order: O(m*b)

Avoiding repeated states

In increasing order of effectiveness and computational overhead:

- do not return to state we come from, i.e., expand function will skip possible successors that are in same state as node's parent.
- do not create paths with cycles, i.e., expand function will skip possible successors that are in same state as any of node's ancestors.
- do not generate any state that was ever generated before, by keeping track (in memory) of every state generated, unless the cost of reaching that state is lower than last time we reached it.

Depth-limited search

Is a depth-first search with depth limit /

Implementation:

Nodes at depth / have no successors.

Complete: if cutoff chosen appropriately then it is guaranteed to find a solution.

Optimal: it does not guarantee to find the least-cost solution

Iterative deepening search

| Function Iterative-deepening-Search(problem) returns a solution, or failure |
|---|
| for $depth = 0$ to ∞ do |
| result ← Depth-Limited-Search(problem, depth) |
| if <i>result</i> succeeds then return <i>result</i> |
| end |
| return failure |
| |

Combines the best of breadth-first and depth-first search strategies.

- Completeness: Yes,
- Time complexity: O(b^d)
- Space complexity: *O(bd)*
- Optimality: Yes, if step cost = 1

Romania with step costs in km

CS 561, Lectures 3-5

Iterative deepening complexity

- Iterative deepening search may seem wasteful because so many states are expanded multiple times.
- In practice, however, the overhead of these multiple expansions is small, because most of the nodes are towards leaves (bottom) of the search tree:

thus, the nodes that are evaluated several times (towards top of tree) are in relatively small number.

- In iterative deepening, nodes at bottom level are expanded once, level above twice, etc. up to root (expanded d+1 times) so total number of expansions is:
 (d+1)1 + (d)b + (d-1)b^2 + ... + 3b^(d-2) + 2b^(d-1) + 1b^d = O(b^d)
- In general, iterative deepening is preferred to depth-first or breadth-first when search space large and depth of solution not known.

Bidirectional search

- Both search forward from initial state, and backwards from goal.
- Stop when the two searches meet in the middle.
- Problem: how do we search backwards from goal??
 - predecessor of node n = all nodes that have n as successor
 - this may not always be easy to compute!
 - if several goal states, apply predecessor function to them just as we applied successor (only works well if goals are explicitly known; may be difficult if goals only characterized implicitly).
 - for bidirectional search to work well, there must be an efficient way to check whether a given node belongs to the other search tree.
 - select a given search algorithm for each half.

CS 561, Lectu

Comparing uninformed search strategies

| Criterion | Breadth- first | Uniform cost | Depth- first | Depth- limited | Iterative deepening | Bidirectional (if applicable) |
|-----------|-------------------|-----------------|-----------------|-------------------|---------------------|----------------------------------|
| Time | b^d | b^d | b^m | b^l | b^d | b^(d/2) |
| Space | b^d | b^d | bm | bl | bd | b^(d/2) |
| Optimal? | Yes | Yes | No | No | Yes | Yes |
| Complete | ? Yes | Yes | No | Yes if l≥d | Yes | Yes |

- *b* max branching factor of the search tree
- *d* depth of the least-cost solution
- *m* max depth of the state-space (may be infinity)
- /- depth cutoff

Summary

- Problem formulation usually requires abstracting away real-world details to define a state space that can be explored using computer algorithms.
- Once problem is formulated in abstract form, complexity analysis helps us picking out best algorithm to solve problem.
- Variety of uninformed search strategies; difference lies in method used to pick node that will be further expanded.
- Iterative deepening search only uses linear space and not much more time than other uniformed search strategies.
