About this publication

This programmer’s guide provides detailed information regarding the use of the Data Communication and Synchronization library APIs. It contains an overview of the Data Communication and Synchronization library, detailed reference information about the APIs, and usage information for programming with the APIs.

For information about the accessibility features of this product, see Appendix G, “Accessibility features,” on page 105.

Who should use this book

This book is intended for use by accelerated library developers and compute kernel developers.

Related information

See “Related documentation” on page 111.

How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information. If you have any comments about this publication, send your comments using Resource Link™ at [http://www.ibm.com/servers/resourcelink](http://www.ibm.com/servers/resourcelink). Click Feedback on the navigation pane. Be sure to include the name of the book, the form number of the book, and the specific location of the text you are commenting on (for example, a page number or table number).
Chapter 1. Overview

The Data Communication and Synchronization (DaCS) library provides a set of services which ease the development of applications and application frameworks in a heterogeneous multi-tiered system (for example a 64 bit x86 system (x86_64) and one or more Cell BE systems). The DaCS services are implemented as a set of APIs providing an architecturally neutral layer for application developers on a variety of multi-core systems. One of the key abstractions that further differentiates DaCS from other programming frameworks is a hierarchical topology of processing elements, each referred to as a DaCS Element (DE). Within the hierarchy each DE can serve one or both of the following roles:

A general purpose processing element, acting as a supervisor, control or master processor. This type of element usually runs a full operating system and manages jobs running on other DEs. This is referred to as a Host Element (HE).

A general or special purpose processing element running tasks assigned by an HE. This is referred to as an Accelerator Element (AE).

DaCS on Hybrid

DaCS on Hybrid (DaCSH) is an implementation of the DaCS API specification which supports the connection of an HE on an x86_64 system to one or more AEs on Cell Broadband Engines (CBEs). In SDK 3.0, DaCSH only supports the use of sockets to connect the HE with the AEs. Direct access to the Synergistic Processor Elements (SPEs) on the CBE is not provided. Instead DaCSH provides access to the PowerPC® Processor Element (PPE), allowing a PPE program to be started and stopped and allowing data transfer between the x86_64 system and the PPE. The SPEs can only be used by the program running on the PPE.

The program running on the PPE to work with the SPEs can also be a DaCS program. In this case the program will use DaCS on Cell (DaCSC - see DaCS Programmer’s Guide and API Reference for Cell BE); the PPE will act as an AE for DaCSH (communicating with the x86_64 system) and as an HE for DaCSC (communicating with the SPEs). The DaCS API on the PPE is supported by a combined library which, when the PPE is being used with both DaCSH and DaCSC, will automatically use the parameters passed to the API to determine if the PPE is an AE talking to its HE (DaCSH) or an HE talking to its AEs (DaCSC).

In order to manage the interactions between the HE and the AEs DaCSH starts a service on each of them. On the host system the service is the Host DaCS daemon (hdacsd) and on the accelerator the service is the Accelerator DaCS daemon (adacsd). These services are shared between all DaCSH processes for an operating system image. For example, if the x86_64 system has multiple cores that each run a host application using DaCSH, only a single instance of the hdacsd service is needed to manage the interactions of each of the host applications with their AEs via DaCSH. Similarly, on the accelerator, if the CBE is on a Cell Blade (which has two CBEs), a single instance of the adacsd service is needed to managed both of the CBEs acting as AEs, even if they are used by different HEs.

When a host application starts using DaCSH this connects to the hdacsd service. This service manages the system topology from a DaCS perspective (managing reservations) and starts the accelerator application on the AE. Only process management requests will use the hdacsd and adacsd services. All other interactions between the host and accelerator application will flow via a direct
socket connection.

The following diagram provides a summary of the DaCS daemons and their relationships:

where:

- the host application (which uses DaCS) is assumed to be started outside of the scope of DaCS;
- the broad arrow represents the flow of data (since only process management requests are handled by the hdacsd and adacsd services);
- the lines marked ‘socket’ are control socket connections (DaCSd will be a service that is called via ports reserved for DaCS usage. The connections that will be created are between the hdacsd and the adacsd, and between the adacsd and the host application, for stderr and stdout redirection.);
- more than one element (host and accelerator) is shown, as from the perspective of the DaCS services it is shared at an OS installation level (multiple host applications could be using the hdacsd, and multiple accelerator applications could be using the adacsd);
- The stderr and stdout streams of an AE application on the accelerator system are redirected to the HE application.
- For DaCSH the configuration information used for topology management will be retrieved from the file system on the Host Element.
- The hdacsd and adacsd can be configured using configurations files from the file system.
• The DaCSH daemons are user space programs, and are not privileged kernel modules.

**User Ids**

The accelerator application will be started using the user id of the host application. These user ids must already be setup on the accelerator.

---

**Coexistence with DaCS for Cell**

DaCS for Hybrid can coexist and work with DaCS on Cell. To use them both you must install both. For instructions on installing DaCS on Cell see the *SDK 3.0 Installation Guide*.

When both are installed the application using DaCS on the PPU can be both an AE for the x86_64 HE and an HE for the SPU AEs. The DaCS library automatically directs the requests appropriately based on the passed parameters. For example a `dacs_send()` is passed the DE Id and Pid of the destination to send the message to. This is used by the DaCS library to determine if it should be sent to the x86_64 HE using DaCS for Hybrid or to a SPU AE using DaCS for Cell.

All three (x86_64, PPU and SPU) can work together with remote memory and mutexes. When these are created on the PPU they are created in a way that allow them to be used with both the x86_64 HE and the SPU AE. In this way processes on all three can be synchronized using a mutex or can share remote memory. Note, however, that this must be initiated on the PPU (which is shared between the two). It is not possible for the x86_64 HE to create the mutex and share it with the PPU AE and then for the PPU (as an HE) to share it with its SPU AEs. This does not work as a mutex can only be shared by the DE that created it - the x86_64 DE cannot see the SPU DE.

---

**Services**

The DaCS services can be divided into the following categories:

**Resource reservation**

The resource reservation services allow an HE to reserve AEs below itself in the hierarchy. The APIs abstract the specifics of the reservation system (O/S, middleware, etc.) to allocate resources for an HE. Once reserved, the AEs can be used by the HE to execute tasks for accelerated applications.

**Process management**

The process management services provide the means for an HE to execute and manage accelerated applications on AEs, including, but not limited to, remote process launch, remote process termination, and remote error notification.

The host system DaCsd (hdacsd) provides services to the HE applications. The accelerator DaCSD (adacsd) provides services to the hdacsd and HE application, including the launching of the AE applications on the accelerator for the HE applications.

**Group management**

The group management services provide the means to designate dynamic
groups of processes for participation in collective operations. In SDK 3.0 this is limited to process execution synchronization (barrier).

**Remote memory**

The remote memory services provide the means to create, share, transfer data to, and transfer data from a remote memory segment. The data transfers are performed using a one-sided put/get remote direct memory access (rDMA) model. These services also provide the ability to scatter/gather lists of data, and provide optional enforcement of ordering for the data transfers.

**Message passing**

The message passing services provide the means for passing messages asynchronously, using a two-sided send/receive model. Messages are passed point-to-point from one process to another.

**Mailboxes**

The mailbox services provide a simple interface for synchronous transfer of small (32-bit) messages from one process to another.

**Process Synchronization**

The process synchronization services provide the means to coordinate or synchronize process execution. In SDK 3.0 this is limited to the barrier synchronization primitive.

**Data Synchronization**

The data synchronization services provide the means to synchronize and serialize data access. These include management of *wait identifiers* for synchronizing data transfers, as well as *mutex* primitives for data serialization.

**Error Handling**

The error handling services enable the user to register error handlers and gather error information.
Chapter 2. Installing and configuring DaCS

The DaCS library should be installed as a component of the Cell BE Software Development Kit. In order for it to work correctly:

- library path information may need to be set up (by using LD_LIBRARY_PATH or ldconfig) or you may specifically skip this and use RPATH information when linking DaCS applications, and
- daemons are not started immediately after installation and will need to be configured on the host and started on the host and accelerators.

Installation

Several packages are available that provide the means to develop, deploy and debug DaCS applications on your x86_64 and Cell BE system. The following table shows the package names with a short description:

Table 1.

<table>

See the *SDK 3.0 Installation Guide* for detailed installation and configuration information.
Chapter 3. Programming with DaCS

How to compile and build applications which use DaCS

Process Management Model

When working with the host and accelerators there has to be a way to uniquely identify the participants that are communicating. From an architectural perspective, each accelerator could have multiple processes simultaneously running, so it is not enough simply to identify the accelerator. Instead the unit of execution on the accelerator (the DaCS Process) must be identified using its DaCS Element Id (DE id) and its Process Id (Pid). The DE Id is retrieved when the accelerator is reserved (using dacs_reserve_children()) and the Pid when the process is started (using dacs_de_start()). Since the parent is not reserved and a process is not started on it two constants are provided to identify the parent DACS_DE_PARENT and DACS_PID_PARENT. Similarly, to identifying the calling process itself, the constants DACS_DE_SELF and DACS_PID_SELF are provided.

Resource Sharing Model

The APIs supporting the locking primitives, remote memory access, and groups follow a consistent pattern of creation, sharing, usage and destruction:

- Creation: An object is created which will be shared with other DEs, for example with dacs_remote_mem_create().
- Sharing: The object created is then shared by linked share and accept calls. The creator shares the item (for instance with dacs_remote_mem_share()), and the DE it is shared with accepts it (in this example with dacs_remote_mem_accept()). These calls must be paired. When one is invoked it waits for the other to occur. This is done for each DE the share is actioned with.
- Usage: This may require closure (such as in the case of groups) or it the object may immediately be available for use. For instance remote memory can immediately be used for put and get.
- Destruction: The DEs that have accepted an item can release the item when they are done with it (for example by calling dacs_remote_mem_release()). The release does not block, but notifies the creator that it is not longer being used and cleans up any local storage. The creator does a destroy (in this case dacs_remote_mem_destroy()) which will wait for all of the DEs it has shared with to release the item, and then destroy the shared item.

DaCS API functions

The DaCS library API services are provided as functions in the C language. The protocols and constants required are made available to the compiler by including the DaCS header file dacs.h as:

#include <dacs.h>

In general the return value from these functions is an error code (see Appendix F “Error codes,” on page 103). Data is returned within parameters passed to the functions.
Note: Implementations may provide options, restrictions and error codes that are not specified here.

Note: When more than one error condition is present it is not guaranteed which one will be reported.

To make these services accessible to the runtime code each process must create a DaCS environment. This is done by calling the special initialization service dacs_runtime_init(). When this service returns the environment is set up so that all other DaCS function calls can be invoked.

When the DaCS environment is no longer required the process must call dacs_runtime_exit() to free all resources used by the environment.

Building a DaCS application

Three versions of the DaCS libraries are provided with the DaCS packages: optimized, debug and traced. The optimized libraries have minimal error checking and are intended for production use. The debug libraries have much more error checking than the optimized libraries and are intended to be used during application development. The traced libraries are the optimized libraries with performance and debug trace hooks in them. These are intended to be used to debug functional and performance problems that might be encountered. The traced libraries use the interfaces provided by the Performance Debug Tool (PDT) and require that this tool be installed. See Appendix D, “Performance and debug trace,” on page 97 for more information on configuring and using traced libraries, and Appendix C, “DaCS debugging,” on page 91 for debug libraries.

Both static and shared libraries are provided for the x86_64 and PPU. The desired library is selected by linking to the chosen library in the appropriate path. The static library is named libdacs.a, and the shared library is libdacs.so. The locations of these are:

<table>
<thead>
<tr>
<th>Description</th>
<th>PPU Library Path</th>
<th>x86_64 Library Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optimized</td>
<td>/prototype/usr/lib64</td>
<td>/prototype/usr/spu/lib64</td>
</tr>
<tr>
<td>Debug</td>
<td>/prototype/usr/lib64/dacs/debug</td>
<td>/prototype/usr/spu/lib64/dacs/debug</td>
</tr>
<tr>
<td>Traced</td>
<td>/prototype/usr/lib64/dacs/trace</td>
<td>/prototype/usr/spu/lib64/dacs/trace</td>
</tr>
</tbody>
</table>

Affinity requirements for host applications

A hybrid DaCS application on the host (x86_64) must have processor affinity to start. This can be done:

- on the command line,
- in mpirun, or
- through the sched_setaffinity function.

Here is a command line example to set affinity of the shell to the first processor:

```
taskset -p 0x00000001 $$
```
The bit mask, starting with 0 from right to left, is an index to the processor affinity setting. Bit 0 is on or off for CPU 0, bit 1 for CPU 1, and bit number x is CPU number x. $$ means the current process gets the affinity setting.

```
taskset -p $$
```

will return the mask setting as an integer. Using the -c option makes the taskset more usable. For example,

```
taskset -pc 7 $$
```

will set the processor CPU affinity to CPU 7 for the current process. The -pc parameter sets by process and CPU number.

```
taskset -pc $$
```

will return the current CPU setting for affinity for the current process. See the man page for taskset for more details.

To launch a DaCS application use a taskset call, for example:

```
taskset 0x00000001 HelloDaCSApp Mike
```

or equivalently

```
taskset -c 0 HelloDaCSApp Mike
```

where the application program is HelloDaCSApp and is passed an argument of "Mike".

According to the man page for taskset a user must have CAP_SYS_NICE permission to change CPU affinity.

On the accelerator system the adacsd launch of an AE application on a specific CBE includes setting the affinity to the CBE and its associated memory node. If the launch is on the Cell Blade as a resource no affinity is set.
Chapter 4. Initializing the DaCS daemons

Starting and stopping the DaCS services

The daemons can be stopped and started using the shell service command in the /sbin directory. For example, to stop the host daemon type:
/sbin/service hdacsd stop

and to restart the host daemon type:
/sbin/service hdacsd start

The accelerator daemon (adacsd) may be restarted in like manner. See the man page for service for more details on the service command.

DaCS daemon Configuration

The host daemon service is named hdacsd and the accelerator daemon service is named adacsd. Both daemons are configured using their respective /etc/dacsd.conf files.

Default versions of these files are automatically installed with each of the daemons. These default files contain comments on the parameters and values currently supported.

Note:

It is recommended that the configuration files are backed up before making any changes.

When one of these files is changed the changes will not take affect until the respective daemon is restarted as described above.

The default configuration for the daemons will work in most situations. The configuration file contains the following options:

**dacsd_receive_timeout**
- The default receive timeout in seconds. 0 (zero) means no timeout. For example, to set a timeout of 5 seconds use:
dacsd_receive_timeout=5

**dacsd_kill_timeout**
- The default dacs_de_kill timeout; the number of seconds between sending SIGTERM and SIGKILL. 0 (zero) means that dacsd_he_terminate will send SIGKILL immediately, without sending SIGTERM. For example, to set a timeout of 5 seconds use:
dacsd_kill_timeout=5

**blade_monitor_interval**
- The period in seconds between polling Cell Blades to track their availability. Setting this to 0 disables the Cell Blade monitor. For example, to set a period of 60 seconds use:
blade_monitor_interval=60
**dacs_topology_config**
The topology configuration file, for example:
```
dacs_topology_config=/etc/dacs_topology.config
```

**ae_cwd_prefix**
The AE Current Working Directory prefix. Each AE process started by dacs_de_start is given a temporary current working directory named `<ae_cwd_prefix>/adacsd-tmp/<HE # Process Info>/<AE Process Info>`. DaCS applications refer to this by `$AE_CWD` in the dacs_de_start program parameters and environment variables. When adacsd starts it will clear the directory `<ae_cwd_prefix>/adacsd-tmp`. When an AE process ends, adacsd will remove the directory `<ae_cwd_prefix>/adacsd-tmp/<HE Process Info>/<AE Process Info>`. When an HE process ends, adacsd will remove the directory `<ae_cwd_prefix>/adacsd-tmp/<HE Process Info>`. An example of this parameter is:
```
ae_cwd_prefix=/adacsd
```

**ae_cwd_keep**
The default for this is
```
ae_cwd_keep=false
```
which means the AE Current Working Directory and its contents are deleted when the AE process terminates. To prevent this use:
```
ae_cwd_keep=true
```

**he_tar_command**
dacs_de_start transfers files via tar. The tar commands are configurable to help with debugging, but should not normally be changed. Configuring these commands incorrectly will cause dacsd_he_xfer to fail. The default is:
```
he_tar_command="/bin/tar cf -"
```
An example of a debug setting is:
```
he_tar_command="/usr/bin/strace -o/tmp/he_tar_strace /bin/tar cvvf -"
```

**ae_tar_command**
See the he_tar_command. The default for this is:
```
ae_tar_command="/bin/tar xf -"
```
and an example is:
```
ae_tar_command="/usr/bin/strace -o/tmp/ae_tar_strace /bin/tar xvf -"
```

**adacsd_use_numa**
This is a temporary workaround for problems with libnuma versions before 0.9.10. The default is:
```
adacsd_use_numa=true
```
To disable numa support use:
```
adacsd_use_numa=false
```

**Default startup options**
These are:
```
ADACSD_ARGS="--log /var/log/adacsd.log --pidfile /var/run/adacsd.pid"
HDACSD_ARGS="--log /var/log/hdacsd.log --pidfile /var/run/hdacsd.pid"
```

Chapter 5. Initializing and closing down the DaCS library

The `dacs_runtime_init` and `dacs_runtime_exit` services initialize and close down access to the DaCS library.

Call `dacs_runtime_init()` before you use any other DaCS services, and do not use any DaCS services after you have called `dacs_runtime_exit()`.

Calling `dacs_runtime_exit()` on an AE causes the communications between the AE and HE to be stopped. Calling `dacs_runtime_init()` after `dacs_runtime_exit()` will fail because once communications are stopped they can only be initiated by the HE calling `dacs_de_start()` to start a new process.
dacs_runtime_init

NAME

dacs_runtime_init - Initialize all runtime services for DaCS.

SYNOPSIS

DACS_ERR_T dacs_runtime_init ( void *, void * )

Call parameters
All parameters must be set to NULL for SDK 3.0. Passing in a value other than NULL will result in the error DACS_ERR_INVALID_ADDR.

DESCRIPTION

The dacs_runtime_init service initializes all runtime services for DaCS.

Note: This service must be called for every process before any other DaCS services can be used. All other DaCS services will return DACS_ERR_NOT_INITIALIZED if called before this service.
A host process may call this service more than once, provided there is a call to dacs_runtime_exit() in between. An accelerator process may only call this service once, even if there is an intervening call to dacs_runtime_exit().

RETURN VALUE

The dacs_runtime_init service returns an error indicator defined as:
- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: invalid pointer.
- DACS_ERR_NO_RESOURCE: unable to allocate required resources.
- DACS_ERR_INITIALIZED: DaCS is already initialized.
- DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.
- DACS_ERR_VERSION_MISMATCH: version mismatch between library and DaCSd.

USAGE

For debug or performance operations on a remote workstation client pass DACS_START_PARENT to dacs_de_start().

dacs_runtime_init() respects the following environment variables for setting up an event listener for a remote workstation client:
- DACS_LISTENER_HOST: the IP address of the workstation client.
- DACS_LISTENER_PORT: the IP port listening on the workstation client.
- DACS_LISTENER_EVENT: the named event to send to the client workstation:
  - DACS_LISTENER_EVENT=CELL_APP_LISTENER: see dacs_de_start for more details;
  - otherwise, all events are sent to the remote workstation client.

SEE ALSO

dacs_runtime_exit(3)
**dacs_runtime_exit**

**NAME**

dacs_runtime_exit - Close down all runtime services for DaCS.

**SYNOPSIS**

DACS_ERR_T dacs_runtime_exit ( void )

**Parameters**
None

**DESCRIPTION**

The dacs_runtime_exit service closes down and destroys all runtime services, processes, transfers, and memory used by DaCS. After calling this service, no other DaCS services can be used until another dacs_runtime_init() is performed. Calling dacs_runtime_init() after a dacs_runtime_exit() is only support for a host process.

**RETURN VALUE**

The dacs_runtime_exit service returns an error indicator defined as:
- DACS_SUCCESS: normal return.
- DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.

**SEE ALSO**

dacs_runtime_init(3)
Chapter 6. Reservation services

In the DaCS environment, hosts and accelerators have a hierarchical parent-child relationship. This hierarchy forms a logical topology of parents, children, and peers. In SDK 3.0 only child-related APIs are defined and supported.

**dacs_get_num_avail_children**

**NAME**

dacs_get_num_avail_children - Return the number of children of the specified type available to be reserved.

**SYNOPSIS**

DACS_ERR_T dacs_get_num_avail_children (DACS_DE_TYPE_T type, uint32_t *num_children)

Call parameter  

*type*  
The type of children to report. This can be any of:  
- DACS_DE_SYSTEMX,  
- DACS_DE_CELL_BLADE,  
- DACS_DE_CBE, or  
- DACS_DE_SPE.

Return parameter  

*num_children*  
The number of available children. This may be zero if either no children of the requested type exist, or children exist but cannot be reserved.

**DESCRIPTION**

The dacs_get_num_avail_children service returns the number of children of the caller of the specified type that are available for reservation.

**Note:** This service returns the number of children that were available at the time of the call. The actual number can change any time after the call. The number of children is only returned upon success.

**RETURN VALUE**

The dacs_get_num_avail_children service returns an error indicator defined as:  
- DACS_SUCCESS: normal return.  
- DACS_ERR_INVALID_ADDR: invalid pointer.  
- DACS_ERR_INVALID_ATTR: invalid flag or enumerated constant.  
- DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.
SEE ALSO
dacs_reserve_children(3), dacs_release_delist(3)

dacs_reserve_children

NAME
dacs_reserve_children - Reserve children of a specified type.

SYNOPSIS

DACS_ERR_T  dacs_reserve_children ( DACS_DE_TYPE_T  type, uint32_t
*num_children, de_id_t *de_list )

Call parameters

<table>
<thead>
<tr>
<th>type</th>
<th>The type of children to report. This can be any of:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DACS_DE_SYSTEMX,</td>
<td>DACS_DE_CELL_BLADE,</td>
</tr>
<tr>
<td>DACS_DE_CBE,</td>
<td>DACS_DE_SPE.</td>
</tr>
<tr>
<td>*num_children</td>
<td>A pointer to the number of children requested.</td>
</tr>
</tbody>
</table>

Return parameters

| *num_children | A pointer to the number of children actually reserved. This may be less than or equal to the number requested. |
| *de_list      | A pointer to a location where the list of reserved children is returned. The space for this list must be allocated by the caller and must have enough room for num_children entries. |

DESCRIPTION

The dacs_reserve_children service attempts to reserve the requested number of children of the specified type. The actual number reserved may be less than or equal to the number requested. The actual number and list of reserved children is returned to the caller.

RETURN VALUE

The dacs_reserve_children service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ATTR: invalid flag or enumerated constant.
- DACS_ERR_INVALID_ADDR: invalid pointer.
- DACS_ERR_INVALID_SIZE: number of children requested must be greater than zero.
- DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.

SEE ALSO

dacs_get_num_avail_children(3), dacs_release_delist(3)
**dacs_release_de_list**

**NAME**

dacs_release_de_list - Release the reservations for a list of DEs.

**SYNOPSIS**

```c
DACS_ERR_T dacs_release_de_list ( uint32_t num_des, de_id_t *de_list )
```

**Call parameters**

- **num_des**: The number of DEs in the list.
- ***de_list**: A pointer to the list of DEs to release.

**DESCRIPTION**

The `dacs_release_de_list` service releases the reservation for the specified list of DEs. On successful return all DEs in the list are released (made available). On failure none of the DEs in the list are released.

**RETURN VALUE**

The `dacs_release_de_list` service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: invalid pointer.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_RESOURCE_BUSY**: the resource is in use.
- **DACS_ERR_INVALID_SIZE**: invalid list size.
- **DACS_ERR_DACSD_FAILURE**: unable to communicate with DaCSd.

**SEE ALSO**

Chapter 7. Process management

This chapter describes the functions for starting, stopping and monitoring processes on DEs.

Current Working Directory

A key element in process management is the current working directory on the accelerator file system. DaCS internally determines this for the dacs_de_start() call. For environment variables such as PATH or LD_LIBRARY_PATH, the underlying implementation will substitute the current working directory for $AE_CWD.

For example, if the current working directory on the accelerator is /DACS-TMP/HOME/USER then PATH=$AE_CWD:/USR/BIN points to /DACS-TMP/HOME/USER:/USR/BIN on the accelerator file system, and LD_LIBRARY_PATH=$AE_CWD:/DACS_LIB points to /DACS-TMP/HOME/USER:/DACS_LIB.

All files transferred by dacs_de_start() are placed in the current working directory. This will be unique across all AE applications on an accelerator.

When the launched accelerator process terminates, DaCS clears the working directory by default. A configuration option in /etc/dacsd.conf is available to allow retention of the current working directory.

Note: The programmer using LD_LIBRARY_PATH may need to incorporate the DaCS libraries, and any required "so" files, into the environment variable for running accelerator DaCS applications. See the accompanying documentation and readme files for these considerations.

Note: See Appendix C, “DaCS debugging,” on page 91 for how to keep core dumps for launched accelerator applications.

Environment variables in Hybrid DaCS

Hybrid DaCS (tier 1) has specific environment variables in the process issuing the dacs_de_start() call. This allows an external program such as a debugging or profiling tool to be started which in turn starts the accelerator process. These variables are described in “ENVIRONMENT” on page 23.
**NAME**

dacs_de_start - Start a process on a DE.

**SYNOPSIS**

DACS_ERR_T dacs_de_start ( de_id_t de, void *prog, char const **argv, char const **envv, DACS_PROC_CREATION_FLAG_T creation_flags, dacs_process_id_t *pid )

*Call parameters*

- **de**
  The target DE where the program will execute.
- **prog**
  A pointer to the program text to execute. What this points to is platform-dependent, and also dependent on the creation_flags parameter.
- ****argv
  A pointer to an array of pointers to argument strings (the argument list), terminated by a NULL pointer.
- ****envv
  A pointer to an array of pointers to environment variable strings (the environment list), terminated by a NULL pointer.
- **creation_flags**
  An implementation-specific flag that specifies how the executable program is found. This can be any of:
  - DACS_PROC_LOCAL_FILE: a fully qualified pathname,
  - DACS_PROC_LOCAL_FILE_LIST: a list of fully qualified pathnames,
  - DACS_PROC_REMOTE_FILE: a fully qualified path on a remote system, or
  - DACS_PROC_EMBEDDED: the handle of an embedded executable image.

*Return parameter*

- **pid**
  A pointer to a location where the process id is stored on successful return.

**DESCRIPTION**

The dacs_de_start service starts a process on the specified DE. The service can be called several times to start one or more processes on the same DE. The number of processes that can be started on a particular DE is platform and implementation dependent.

**Note:** In the execution environment, the environment variables in DACS_START_ENV_LIST will be a list appended to the environment variables in the list under parameter char const **envv.

**Note:** The use of duplicate environment variables across the lists in the dacs_de_start() service and DAC_START_ENV_LIST is possible. However the value that will be used is implementation dependent, because getenv() is used and what it returns is implementation dependent.

**Note:** Some implementations may prohibit one type of DE from starting processes on another DE. If this situation exists, the dacs_de_start() service returns DACS_ERR_PROHIBITED.
RETURN VALUE

The dacs_de_start service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: a pointer is invalid.
- **DACS_ERR_INVALID_ATTR**: a flag or enumerated constant is invalid.
- **DACS_ERR_NO_RESOURCE**: unable to allocate required resources.
- **DACS_ERR_PROHIBITED**: the operation is prohibited by the implementation.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_TARGET**: the operation is not allowed for the target DE.
- **DACS_ERR_PROC_LIMIT**: the maximum number of processes supported has been reached.
- **DACS_ERR_INVALID_PROG**: the specified program could not be executed.
- **DACS_ERR_INVALID_ARGV**: argv is too large or invalid.
- **DACS_ERR_INVALID_ENV**: envv is too large or invalid.
- **DACS_ERR_DACSD_FAILURE**: unable to communicate with DaCsD.
- **DACS_ERR_SYSTEM**: A system error was encountered. This often indicates the executable file was not found on the remote system.

ENVIRONMENT

Hybrid DaCS has specific environment variables in the process issuing the dacs_de_start() call. This allows an external program such as a debugging or profiling tool to be started which in turn starts the accelerator process.

These variables are:

**DACS_START_PARENT**
specifies the command used to start an auxiliary program which starts the accelerator process. Within the command, %e, %a and %p are replaced respectively by the accelerator executable name, the accelerator arguments, and the parent's listening port value.

For example, given:
```
DACS_START_PARENT="/usr/bin/gdb --args %e %a"
```

then:
```
dacs_de_start (de, "myaccel", "myargs", 0, ppid)
```

would launch the command:
```
/usr/bin/gdb --args myaccel myargs
```

**DACS_START_FILES**
specifies the name of a file which contains a list of files to transfer to the PPE prior to launching the accelerator process. File names are fully-qualified POSIX-compliant pathname files.

**DACS_START_ENV_LIST**
specifies an additional list of environment variables for the initial program spawn on the accelerator. List items are separated by semicolons. An example of the format is:
```
ENV1=VAL1;ENV2=VAL2;QSHLL_*;ENV3
```

where:
• ENV1 and ENV2 are the environment variables and VAL1 and VAL2 are their respective settings,
• QSHELL_* means pull all environment variables prefixed with QSHELL_ from the present environment, and
• ENV3 means pull the environment variable from the present environment and pass on.

Delete functions, such as <name>= and <prefix>*= to drop environment variables by name or prefix, are not supported in SDK 3.0.

DACS_PARENT_PORT
specifies the value of %p to pass in the dacs_de_start() call. This value is post-incremented in the environment so that it is one more on the next dacs_de_start() call.

Note: The port allocated by DACS_PARENT_PORT is solely the responsibility of the environment setter and is not guaranteed to be available on the accelerator OS.

SEE ALSO

dacs_num_processes_supported(3)  dacs_num_processes_running(3)
dacs_de_wait(3)  dacs_de_test(3)
**NAME**

`dacs_num_processes_supported` - Return the number of processes that can be started on a DE.

**SYNOPSIS**

```c
DACS_ERR_T dacs_num_processes_supported ( de_id_t de, uint32_t *num_processes )
```

**Call parameter**

`de` - The DE to query.

**Return parameter**

`*num_processes` - A pointer to a location where the maximum number of processes that can be started on this DE is stored.

**Note:** In SDK 3.0 the value returned in `num_processes` can only be 1 or 0.

**DESCRIPTION**

The `dacs_num_processes_supported` service returns the number of simultaneous processes that can be started on the specified DE. The target DE must have been reserved by the caller.

**RETURN VALUE**

The `dacs_num_processes_supported` service returns an error indicator defined as:

- **DACS_SUCCESS:** normal return.
- **DACS_ERR_INVALID_DE:** the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_ADDR:** the pointer is invalid.
- **DACS_ERR_INVALID_TARGET:** the operation is not allowed for the target de.

**SEE ALSO**

- `dacs_de_start(3)`, `dacs_num_processes_running(3)`, `dacs_de_wait(3)`, `dacs_de_test(3)`
dacs_num_processes_running

NAME

dacs_num_processes_running - Return the number of processes currently running on a DE.

SYNOPSIS

DACS_ERR_T dacs_num_processes_running ( de_id_t de, uint32_t *num_processes )

Call parameter

de The DE to query.

Return parameter

*num_processes A pointer to a location where the number of processes currently running on the target DE is stored.

DESCRIPTION

The dacs_num_processes_running service returns the number of processes currently running on the specified DE. This includes all processes that have been started (with dacs_de_start()) and have not yet had their exit status reaped (with dacs_de_test() or dacs_de_wait()). The target DE must have been reserved by the caller.

RETURN VALUE

The dacs_num_processes_running service returns an error indicator defined as:

• DACS_SUCCESS: normal return.
• DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_INVALID_TARGET: the operation is not allowed for the target DE.

SEE ALSO

[dacs_de_start(3) dacs_num_processes_supported(3) dacs_de_wait(3) dacs_de_test(3)]
NAME

dacs_de_wait - Block the caller waiting for a process running on a DE to finish.

SYNOPSIS

DACS_ERR_T dacs_de_wait ( de_id_t de, dacs_process_id_t pid, int32_t *exit_status )

Call parameters

de The target DE.

pid The target process.

Return parameter

*exit_status A pointer to a location where the exit code is stored (if
DACS_STS_PROC_FINISHED or DACS_STS_PROC_FAILED) or the
signal number (if DACS_STS_PROC_ABORTED).

DESCRIPTION

The dacs_de_wait service returns the status of the target process, if it was
successful, or an error code. If the process is running at the time of the call, the
call blocks until it finishes execution. If the process has finished execution at the
time of the call, the call does not block.

When this service or dacs_de_test() detects a finished, failed, or aborted status,
the status is reaped. Once the status of a process has been reaped, subsequent calls
to query its status will fail with DACS_ERR_INVALID_PID.

RETURN VALUE

The dacs_de_wait service returns an error indicator defined as:

• DACS_STS_PROC_FINISHED: the process finished execution without error.
• DACS_STS_PROC_FAILED: the process exited with a failure.
• DACS_STS_PROC_ABORTED: the process terminated abnormally. The
  platform-specific exception code is returned in exit_status. For Linux/UNIX this
  is the signal number which caused the termination.
• DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
• DACS_ERR_INVALID_PID: the specified PID does not refer to a valid process.
• DACS_ERR_INVALID_TARGET: the operation is not allowed for the target process.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.

SEE ALSO

dacs_de_start(3) dacs_num_processes_supported(3)
dacs_num_processes_running(3) dacs_de_test(3)
NAME

dacs_de_test - Test the status of a process.

SYNOPSIS

DACS_ERR_T dacs_de_test ( de_id_t de, dacs_process_id_t pid, int32_t *exit_status )

Call parameters

de The target DE.

pid The target process.

Return parameter

*exit_status A pointer to a location where the exit code is stored (if DACS_STS_PROC_FINISHED or DACS_STS_PROC_FAILED) or the signal number (if DACS_STS_PROC_ABORTED).

Note: If the return value is DACS_STS_PROC_RUNNING then the exit_status is not modified.

DESCRIPTION

The dacs_de_test service returns the status of the target process, if it was successful, or an error code.

When this service or dacs_de_wait() detects a finished, failed, or aborted status, the status is reaped. Once the status of a process has been reaped, subsequent calls to query its status will fail with DACS_ERR_INVALID_PID.

RETURN VALUE

The dacs_de_test service returns an error indicator defined as:

• DACS_STS_PROC_RUNNING: the process is still running.
• DACS_STS_PROC_FINISHED: the process finished execution without error.
• DACS_STS_PROC_FAILED: the process exited with a failure.
• DACS_STS_PROC_ABORTED: the process terminated abnormally. The platform-specific exception code is returned in exit_status. For Linux/UNIX this is the signal number which caused the termination.
• DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
• DACS_ERR_INVALID_PID: the specified PID does not refer to a valid process.
• DACS_ERR_INVALID_TARGET: the operation is not allowed for the target process.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_DACSD_FAILURE: unable to communicate with DaCSd.

Chapter 8. Group functions

Group functions allow you to organize processes into groups so that they can be treated as a single entity.

Definitions

Group

A group is a collection of related processes that share a common set of resources. A process is an identifiable unit of execution.

A group is referred to by a handle. The handle may be a pointer, offset, index or any other unique identifier of the group.

Group Member

A group member is a process, uniquely identifiable by its DE and PID combination.

The members of a group work together to perform a common task, through the use of shared resources. Being a member of a group requires participation in group activities.

Group design

Membership

In DaCS membership is by invitation only. A process cannot declare itself a member of a group; it must be added by the group creator. This works on the basis that the creator of a group resource knows which processes will be participating in the use of the resource. The member being added to a group must also cooperate by accepting membership, and must make a request to leave a group.

Group Leader/Owner

Groups can only be created on an HE. The HE, by creating a group, implicitly becomes the group owner. This does not imply membership or participation in the group. The group owner is responsible for adding and removing members from the group. It is also responsible for allocating resources to be shared with the group. When the group is no longer needed, and all members have left, the owner then has the responsibility of destroying the group.

When DaCS for Hybrid is working with DaCS for Cell, creation of a group on a PPU is done in the PPU’s role as an HE. This means that only it and the SPU AE can be members of the group. Trying to share the group with the x86_64 HE (which is done as a PPU AE) will fail.

Barriers

Certain resources require a group in order to work properly. One such resource is a barrier. Without a known and fixed set of participants barriers cannot work properly. For this reason the concept of groups is necessary.
Barriers provide synchronization of a fixed number of participants. Groups are required in order for the barrier functionality to properly track barrier quora. Barriers are an implied resource associated with being in a group; they are not allocated, initialized, shared or destroyed.

**Group usage scenario**

Group operations can be classified into three stages: initialization, operation and termination. An example showing the services used in these stages follows.

**Initialization**

The following steps, in this order, would be used by the group owner and members to create and join a group.

<table>
<thead>
<tr>
<th>Owner</th>
<th>Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the group: <code>dacs_group_init( &amp;group, flags );</code></td>
<td>Accept their addition, individually: <code>dacs_group_accept( de, pid, group );</code></td>
</tr>
<tr>
<td>This creates an opaque group handle. The handle will then be used by all members during group operations.</td>
<td></td>
</tr>
<tr>
<td>Add members (identified by DE and PID) to the group, one by one: <code>dacs_group_add_member( de, pid, group );</code></td>
<td></td>
</tr>
<tr>
<td>(Optional) Add itself to the group: <code>dacs_group_add_member( DACS_DE_SELF, DACS_PID_SELF, group );</code></td>
<td></td>
</tr>
<tr>
<td>(This does not require an accept response.)</td>
<td></td>
</tr>
<tr>
<td>Close the initialization of the group: <code>dacs_group_close( group );</code></td>
<td></td>
</tr>
</tbody>
</table>

**Operation**

Group operations are controlled by barriers. These are used to synchronize the processing by different members of the group. If it is necessary to ensure that no member enters a new stage of processing before other members are ready then each member must make a call: Each member will then be blocked until all members have made this call. When the last member is accounted for all members will be released.

<table>
<thead>
<tr>
<th>Owner</th>
<th>Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait on barrier, individually: <code>dacs_barrier_wait( group );</code></td>
<td></td>
</tr>
</tbody>
</table>

**Termination**

The following steps, in this order, would be used by the group owner and members to remove a group.
<table>
<thead>
<tr>
<th>Owner</th>
<th>Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destroy the group:</td>
<td>Leave the group, individually:</td>
</tr>
<tr>
<td>dacs_group_destroy( group );</td>
<td>dacs_group_leave( group );</td>
</tr>
</tbody>
</table>

## Group owner functions

**dacs_group_init**

**NAME**

dacs_group_init - Initialize a DaCS group.

**SYNOPSIS**

DACS_ERR_T dacs_group_init ( dacs_group_t *group, uint32_t flags )

**Call parameter**
flags

**Flags for group initialization.**

**Return parameter**
*group

**A pointer to a group handle which is filled in upon successful return.**

**Note:** In SDK 3.0 no flags will be supported and the flags value passed in must be zero.

**DESCRIPTION**

The dacs_group_init service initializes a DaCS group and returns a handle to the group. The calling process is the owner of the group. The owner process is not a member of the group by default, but may add itself as a member.

**RETURN VALUE**

The dacs_group_init service returns an error indicator defined as:
- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
- DACS_ERR_NO_RESOURCE: could not allocate required resources.

**SEE ALSO**

- dacs_group_add_member(3)
- dacs_group_close(3)
- dacs_group_destroy(3)
- dacs_group_accept(3)
- dacs_group_leave(3)
- dacs_barrier_wait(3)
**dacs_group_add_member**

**NAME**

dacs_group_add_member - Add a member to a DaCS group.

**SYNOPSIS**

```c
DACS_ERR_T dacs_group_add_member ( de_id_t de, dacs_process_id_t pid, dacs_group_t group )
```

**Call parameters**

- **de**
  - The DE ID of the member to add. The group owner may specify a value of DACS_DE_SELF to add itself.
- **pid**
  - The process ID of the member to add. The group owner may specify a value of DACS_PID_SELF to add itself.
- **group**
  - The handle of the group to which the new member is to be added.

**DESCRIPTION**

The `dacs_group_add_member` service adds the specified `de/pid` as a member of the specified group. This service can only be called by the process which owns the group. If the owner process is adding itself the service returns immediately. If the member to be added is not the owner of the group this service blocks, waiting for an associated `dacs_group_accept()` call from the new member.

**RETURN VALUE**

The `dacs_group_add_member` service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_HANDLE**: the group handle does not refer to a valid group.
- **DACS_ERR_INVALID_TARGET**: this operation is not allowed for the target process.
- **DACS_ERR_GROUP_CLOSED**: the group is closed.
- **DACS_ERR_GROUP_DUPLICATE**: the specified process is already a member of the specified group.
- **DACS_ERR_NORESOURCE**: unable to allocate required resources.

**SEE ALSO**

- `dacs_group_init(3)`
- `dacs_group_close(3)`
- `dacs_group_destroy(3)`

- `dacs_barrier_wait(3)`

---

32 DaCS for Hybrid-x86 Programmer's Guide and API Reference - DRAFT
dacs_group_close

NAME

dacs_group_close - Close a DaCS group.

SYNOPSIS

DACS_ERR_T dacs_group_close ( dacs_group_t group )

Call parameter
group The handle of the group to close.

DESCRIPTION

The dacs_group_close service closes the initialization of the specified group. Once closed, new members cannot be added to the group. The specified group must have been initialized with dacs_group_init(). This service may only be called by the owner of the group. Group collective operations will block until the group is closed.

RETURN VALUE

The dacs_group_close service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_HANDLE**: the group handle does not refer to a valid group.
- **DACS_ERR_NOT_OWNER**: the caller is not the owner of the group.
- **DACS_ERR_GROUP_CLOSED**: the group is already closed.

SEE ALSO

- dacs_group_init(3)
- dacs_group_add_member(3)
- dacs_group_destroy(3)
- dacs_group_accept(3)
- dacs_group_leave(3)
- dacs_barrier_wait(3)
**dacs_group_destroy**

**NAME**

dacs_group_destroy - Remove a DaCS group.

**SYNOPSIS**

DACS_ERR_T dacs_group_destroy ( dacs_group_t *group )

Call parameter

*group A pointer to the handle of the group to remove.

**DESCRIPTION**

The dacs_group_destroy service removes the specified group and invalidates the handle. This service may only be called by the owner of the group, and blocks until all other members have left the group. If the calling process is the owner of the group and also a member of the group it is implicitly removed from the group when it is destroyed.

**RETURN VALUE**

The dacs_group_destroy service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_HANDLE: the group handle does not refer to a valid group.
- DACS_ERR_NOT_OWNER: the caller is not the owner of the group.
- DACS_ERR_GROUP_OPEN: the group has not been closed.

- dacs_barrier_wait(3)

---

**Group member functions**

Group member functions allow processes to join or leave groups created by other processes.
**dacs_group_accept**

**NAME**

dacs_group_accept - Accept membership to a DaCS group.

**SYNOPSIS**

DACS_ERR_T dacs_group_accept ( de_id_t de, dacs_process_id_t pid, dacs_group_t *group )

Call parameters
  de             The DE ID of the group owner.
  pid            The process ID of the group owner.

Return parameter
  *group       A pointer to the handle of the group to be filled in.

**DESCRIPTION**

The dacs_group_accept service accepts membership to a group and returns the group handle. For each dacs_group_accept() call there must be an associated dacs_group_add_member() call by the owner of the group. This service blocks until the caller has been added to the group by the group owner.

**RETURN VALUE**

The dacs_group_accept service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified pid does not refer to an active process.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_TARGET**: the operation not allowed for the target process.

**SEE ALSO**

- dacs_group_init(3), dacs_group_add_member(3), dacs_group_close(3)
- dacs_group_destroy(3), dacs_group_leave(3), dacs_barrier_wait(3)
**dacs_group_leave**

**NAME**

dacs_group_leave - Request from a member to leave a DaCS group.

**SYNOPSIS**

DACS_ERR_T dacs_group_leave ( dacs_group_t *group )

Call parameter

*group                         A pointer to the handle of the group to leave.

**DESCRIPTION**

The dacs_group_leave service removes the calling process from the specified group. All members other than the owner must leave the group before it can be destroyed. The specified group handle is invalidated upon successful return. This service does not block unless the group is not yet closed.

**RETURN VALUE**

The dacs_group_leave service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_HANDLE: the group handle does not refer to a valid DaCS group.
- DACS_ERR_OWNER: the owner of the group may not leave it.

**SEE ALSO**

[dacs_group_init(3), dacs_group_add_member(3), dacs_group_close(3), dacs_group_destroy(3), dacs_group_accept(3), dacs_barrier_wait(3)]

**Process synchronization**

The process synchronization services provide a means to coordinate or synchronize process execution.
**dacs_barrier_wait**

**NAME**

dacs_barrier_wait - Synchronize members of a group.

**SYNOPSIS**

```c
DACS_ERR_T dacs_barrier_wait ( dacs_group_t group )
```

*Call parameter group*  
The handle of the group with which to synchronize.

**DESCRIPTION**

The `dacs_barrier_wait` service blocks the caller on a group barrier until all members in the group have reached the barrier. The caller must be a member of the specified group.

**RETURN VALUE**

The `dacs_barrier_wait` service returns an error indicator defined as:

- `DACS_SUCCESS`: normal return.
- `DACS_ERR_INVALID_HANDLE`: the group handle does not refer to a valid DaCS group.

**SEE ALSO**

Chapter 9. Data communication

The data communication services transfer data from one process to another. To accommodate transfers across systems with different data representation formats (endian-ness), the services provide an option for byte swapping. The types of byte swapping supported are:

- **DACS_BYTE_SWAP_DISABLE**
  - no byte-swapping.
- **DACS_BYTE_SWAP_HALF_WORD**
  - byte-swapping for halfwords (2 bytes).
- **DACS_BYTE_SWAP_WORD**
  - byte-swapping for words (4 bytes).
- **DACS_BYTE_SWAP_DOUBLE_WORD**
  - byte-swapping for double words (8 bytes).

Different platforms and implementations may also have different alignment restrictions for the data being transferred. The data communication services will return the **DACS_ERR_NOTAligned** error code when those alignment restrictions are not met.

The data communication services require that the caller specify either the source or destination DE and PID, as appropriate. As a convenience to the programmer, the special values **DACS_DE_PARENT** and **DACS_PID_PARENT** are defined, which can be used to refer to the parent DE and PID respectively. The special values **DACS_DE_SELF** and **DACS_PID_SELF** are also provided for those interfaces where the caller is the target of the operation.

**Note:** In SDK 3.0 direct communication is only allowed between a parent and its children. Attempts to communicate to a process which is not the parent or child of the initiator will result in an error of **DACS_ERR_INVALID_TARGET**.

Three different data communication models are supported: remote direct memory access (rDMA), message passing, and mailboxes.

**Remote Direct Memory Access (rDMA)**

**Managing Remote Memory.**

The remote memory management services provide the means for sharing memory regions with remote processes. A memory region is made available to remote consumers using a *share/accept* model whereby the owner of the memory creates and shares a remote memory handle which is then accepted and used by remote processes.

**Note:** With the exception of **dacs_remote_mem_query()**, the DaCS memory transfer services can only be used by the remote processes, and only after they have accepted a share. The owner of the shared memory cannot use these services.

**Note:** When DaCS for Hybrid is being used with DaCS for Cell, remote memory that is created on the PPU (using **dacs_remote_mem_create()**) can be shared with both the x86_64 (HE) and with the SPUs (AEs). If this is done then either can use
the put or get services to get from the memory shared by the PPU.

**dacs_remote_mem_create**

**NAME**

dacs_remote_mem_create - Designate a region in the memory space of the current process for access by remote processes.

**SYNOPSIS**

```c
DACS_ERR_T dacs_remote_mem_create ( void *addr, uint64_t size, DACS_MEMORY_ACCESS_MODE_T access_mode, dacs_remote_mem_t *mem )
```

**Call parameters**

- `*addr` A pointer to the base address of the memory region to be shared.
- `size` The size of the memory region in bytes.
- `access_mode` The access mode to be given to the memory region. This may be:
  - DACS_READ_ONLY,
  - DACS_WRITE_ONLY, or
  - DACS_READ_WRITE.

**Return parameter**

- `*mem` A pointer to a remote memory handle to be filled in.

**DESCRIPTION**

The dacs_remote_mem_create service creates and returns a handle associated with the given memory region. The returned handle can be used with the dacs_remote_mem_share() and dacs_remote_mem_accept() services to share and gain access to remote shared memory.

**RETURN VALUE**

The service dacs_remote_mem_create returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
- DACS_ERR_NO_RESOURCE: unable to allocate required resources.
- DACS_ERR_INVALID_SIZE: a size of zero was requested.

**SEE ALSO**

- dacs_remote_mem_share(3)
- dacs_remote_mem_accept(3)
- dacs_remote_mem_release(3)
- dacs_remote_mem_destroy(3)
- dacs_remote_mem_query(3)
dacs_remote_mem_share

NAME

dacs_remote_mem_share - Pass a memory handle from the current process to a remote process.

SYNOPSIS

DACS_ERR_T dacs_remote_mem_share ( de_id_t dst_de, dacs_process_id_t dst_pid, dacs_remote_mem_t mem )

Call parameters

dst_de The target DE for the share.
dst_pid The target process for the share.
mem The handle of the remote memory to be shared.

DESCRIPTION

The dacs_remote_mem_share service shares the specified remote memory handle from the current process to the remote process specified by dst_de and dst_pid. This service then blocks, waiting for a matching call to the dacs_remote_mem_accept service on the remote side.

RETURN VALUE

The dacs_remote_mem_share service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
- DACS_ERR_INVALID_PID: the specified PID does not refer to an active process.
- DACS_ERR_INVALID_TARGET: this operation is not allowed for the target process.
- DACS_ERR_INVALID_HANDLE: the remote memory handle is invalid.
- DACS_ERR_NOT_OWNER: this operation is only valid for the owner of the resource.

**dacs_remote_mem_accept**

**NAME**

dacs_remote_mem_accept - Accept a memory handle from a remote process.

**SYNOPSIS**

```c
DACS_ERR_T dacs_remote_mem_accept ( de_id_t src_de, dacs_process_id_t src_pid, dacs_remote_mem_t *mem )
```

**Call parameters**

- **src_de**
  The source DE which is sharing the remote memory handle.

- **src_pid**
  The source process which is sharing the remote memory handle.

**Return parameter**

- ***mem**
  A pointer to the accepted memory handle.

**DESCRIPTION**

The `dacs_remote_mem_accept` service blocks the caller until it receives a remote memory handle from an associated `dacs_remote_mem_share()` call. The remote memory handle is filled in upon successful return.

**RETURN VALUE**

The `dacs_remote_mem_accept` service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET**: this operation is not allowed for the target process.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_NO_RESOURCE**: unable to allocate the required resources.

**SEE ALSO**

- [dacs_remote_mem_create(3)]

- [dacs_remote_mem_release(3)]
- [dacs_remote_mem_destroy(3)]
- [dacs_remote_mem_query(3)]
dacs_remote_mem_release

NAME

dacs_remote_mem_release - Release a previously accepted remote memory handle.

SYNOPSIS

DACS_ERR_T dacs_remote_mem_release ( dacs_remote_mem_t *mem )

Call parameter
*mem A pointer to the remote memory handle.

DESCRIPTION

The dacs_remote_mem_release service releases a previously accepted remote memory object and invalidates the handle. When all accepters have released the object it may be destroyed by its owner. This service does not block.

RETURN VALUE

The dacs_remote_mem_release service returns an error indicator defined as:
• DACS_SUCCESS: normal return.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_INVALID_HANDLE: the specified handle does not refer to a valid remote memory object.
• DACS_ERR_OWNER: this operation is not valid for the owner of the resource.

dacs_remote_mem_destroy

NAME

dacs_remote_mem_destroy - Invalidate sharing of a specified memory region.

SYNOPSIS

DACS_ERR_T dacs_remote_mem_destroy ( dacs_remote_mem_t *mem )

Call parameter

*mem                A pointer to a remote memory handle.

DESCRIPTION

The dacs_remote_mem_destroy service invalidates the sharing of a specific memory region which has been created by dacs_remote_mem_create(). Only the creator of the memory region may destroy it. This service blocks until all users of the memory region have released it.

RETURN VALUE

The dacs_remote_mem_destroy service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_HANDLE: the remote memory handle is invalid.
- DACS_ERR_NOT.Owner: this operation is only valid for the owner of the resource.

dacs_remote_mem_query

NAME

dacs_remote_mem_query - Query the attributes of a remote memory region.

SYNOPSIS

DACS_ERR_T dacs_remote_mem_query ( dacs_remote_mem_t mem,
DACS_REMOTE_MEM_ATTR_T attr, uint64_t *value )

Call parameters
mem The handle of the remote memory area to query.
attr The attribute to be queried. This may be one of:
   DACS_REMOTE_MEM_SIZE,
   DACS_REMOTE_MEM_ADDR, or
   DACS_REMOTE_MEM_ACCESS_MODE.

Return parameter
*value A pointer to the location where the attribute value is to be
 returned. If the requested attribute is
 DACS_REMOTE_MEM_ACCESS_MODE, the output value will
 be one of:
   DACS_READ_ONLY,
   DACS_WRITE_ONLY, or
   DACS_READ_WRITE.

DESCRIPTION

The dacs_remote_mem_query service queries the attributes of the specified remote
memory region. The memory region being queried must have been created or
accepted by the caller.

RETURN VALUE

The dacs_remote_mem_query service returns an error indicator defined as:
• DACS_SUCCESS: normal return.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
• DACS_ERR_INVALID_HANDLE: the specified handle is invalid.

rDMA block transfers

The DMA services provide a means to perform direct memory accesses to and
from remote memory.
dacs_put
NAME

dacs_put - Initiate a data transfer from local memory to remote memory.

SYNOPSIS

DACS_ERR_T dacs_put ( dacs_remote_mem_t dst_remote_mem, uint64_t dst_remote_mem_offset, void *src_addr, uint64_t size, dacs_wid_t wid, DACS_ORDER_ATTR_T order_attr, DACS_BYTE_SWAP_T swap )

Call parameters

dst_remote_mem The remote memory handle of the destination buffer.
dst_remote_mem_offset The offset into the remote buffer where the put is to be performed.
*src_addr A pointer to the source memory buffer.
size The size of the transfer.
wid The communications wait identifier.
order_attr An ordering attribute. Possible values are:
  • DACS_ORDER_ATTR_FENCE: execution of this operation is delayed until all previously issued DMA operations to the same DE using the same wid have completed.
  • DACS_ORDER_ATTR_BARRIER: execution of this command and all subsequent DMA operations are delayed until all previously issued DMA operations to the same DE using the same wid have completed.
  • DACS_ORDER_ATTR_NONE: no ordering is enforced.
swap The little-endian or big-endian byte-swapping flag. Possible values are:
  • DACS_BYTE_SWAP_DISABLE,
  • DACS_BYTE_SWAP_HALF_WORD,
  • DACS_BYTE_SWAP_WORD or
  • DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

DESCRIPTION

The dacs_put service initiates data transfer from the caller memory, specified by src_addr, to the target memory, specified by dst_remote_mem and remote_mem_offset. This operation is non-blocking (the call initiates the transfer, but the transfer may continue after the call returns). To ensure that the transfer has completed on the DE, so that the local buffer can be reused or changed, you should issue a call to dacs_wait() or dacs_test() with the same wait identifier.

The target remote memory region must have been previously accepted by the caller with a call to dacs_remote_mem_accept().

Note: The user of the dacs_put() and dacs_get() methods is the process that accepted the memory handle. The owner of the remote memory cannot use these functions.
RETURN VALUE

The dacs_put service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_BUF_OVERFLOW: the buffer has overflowed - the specified offset or size exceed the bounds of the target buffer.
- DACS_ERR_NOTAligned: the buffer is not aligned correctly for the size of the transfer.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
- DACS_ERR_INVALID_SIZE: the size was zero or not supported by the platform.
- DACS_ERR_INVALID_WID: the wait identifier is invalid.
- DACS_ERR_INVALID_HANDLE: the remote memory handle is invalid.
- DACS_ERR_NO_PERM: the resource attributes do not allow this operation.

SEE ALSO

[dacs_get(3) dacs_put_list(3) dacs_get_list(3) dacs_test(3) dacs_wait(3)]
dacs_get

NAME

dacs_get - Get data from remote memory to local memory.

SYNOPSIS

DACS_ERR_T dacs_get ( void *dst_addr, dacs_remote_mem_t src_remote_mem,
uint64_t src_remote_mem_offset, uint64_t size, dacs_wid_t wid,
DACS_ORDER_ATTR_T order_attr, DACS_BYTE_SWAP_T swap )

Call parameters
*dst_addr
A pointer to the base address of the destination memory buffer.

src_remote_mem
The remote memory handle of the source buffer.

src_remote_mem_offset
The offset into the remote buffer where the get is to start.

size
The size of the transfer.

wid
A communications wait identifier.

order_attr
An ordering attribute. Possible values are:
- DACS_ORDER_ATTR_FENCE: execution of this operation is
  delayed until all previously issued DMA operations to the
  same DE using the same wid have completed.
- DACS_ORDER_ATTR_BARRIER: execution of this command and
  all subsequent DMA operations are delayed until all
  previously issued DMA operations to the same DE using the
  same wid have completed.
- DACS_ORDER_ATTR_NONE: no ordering is enforced.

swap
The little-endian or big-endian byte-swapping flag. Possible values are:
- DACS_BYTE_SWAP_DISABLE,
- DACS_BYTE_SWAP_HALF_WORD,
- DACS_BYTE_SWAP_WORD or
- DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

DESCRIPTION

The dacs_get service returns data from the target memory, specified by
src_remote_mem and src_remote_mem_offset, to the caller memory, specified by
dst_addr. This operation is non-blocking (the call initiates the transfer, but the
transfer may continue after the call returns). To ensure that the transfer has
completed you should issue a call to dacs_wait() or dacs_test() with the same
wait identifier.

The target remote memory region must have been previously accepted by the
caller using a call to dacs_remote_mem_accept().

Note: The user of the dacs_put() and dacs_get() methods is the process that
accepted the memory handle. The owner of the remote memory cannot use these
functions.
RETURN VALUE

The dacs_get service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_BUF_OVERFLOW: the buffer has overflowed - the specified offset and size exceed the bounds of the target buffer.
- DACS_ERR_NOT_ALIGNED: the buffer is not aligned properly for its size.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
- DACS_ERR_INVALID_SIZE: the size is zero or not supported by the platform.
- DACS_ERR_INVALID_WID: the wait identifier is invalid.
- DACS_ERR_INVALID_HANDLE: the remote memory handle is invalid.
- DACS_ERR_NO_PERM: the resource attributes do not allow this operation.

SEE ALSO

dacs_put(3) dacs_put_list(3) dacs_get_list(3) dacs_test(3) dacs_wait(3)

rDMA list transfers

The DMA list services enable scatter/gather operations between non-contiguous regions of memory and one contiguous region of memory.

The list services operate on DMA list elements. A list element is defined as a tuple (offset, size), where offset is a 64-bit offset into the remote memory block, and size is the size of the block.
**dacs_put_list**

**NAME**

dacs_put_list - Push data from local memory blocks to a remote memory area.

**SYNOPSIS**

```c
DACS_ERR_T dacs_put_list ( dacs_remote_mem_t dst_remote_mem,
  dacs_dma_list_t *dst_dma_list, uint32_t dst_list_size, void *src_addr, dacs_dma_list_t *src_dma_list,
  uint32_t src_list_size, dacs_wid_t wid, DACS_ORDER_ATTR_T order_attr, DACS_BYTE_SWAP_T swap )
```

Call parameters

- **dst_remote_mem**
  The remote memory handle for the destination buffer.
- **dst_dma_list**
  A pointer to a list of entries describing the transfer locations in the destination buffer.
- **dst_list_size**
  The number of elements in the destination DMA list.
- **src_addr**
  The base address of the source memory buffer.
- **src_dma_list**
  A pointer to a list of entries describing the transfer locations in the source buffer.
- **src_list_size**
  The number of elements in the source DMA list.
- **wid**
  The communications wait identifier associated with this transfer.
- **order_attr**
  Ordering attribute. Possible values are:
  - DACS_ORDER_ATTR_FENCE: execution of this operation is delayed until all previously issued DMA operations to the same DE using the same wid have completed.
  - DACS_ORDER_ATTR_BARRIER: execution of this operation and all subsequent DMA operations are delayed until all previously issued DMA operations to the same DE using the same wid have completed.
  - DACS_ORDER_ATTR_NONE: no ordering is enforced.
- **swap**
  The little-endian or big-endian byte-swapping flag. Possible values are:
  - DACS_BYTE_SWAP_DISABLE,
  - DACS_BYTE_SWAP_HALF_WORD,
  - DACS_BYTE_SWAP_WORD or
  - DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

**DESCRIPTION**

The dacs_put_list service pushes data from the memory blocks specified in the src_dma_list to the remote memory area referenced by the dst_remote_mem handle using the specified dst_dma_list. The interface supports the specification of two DMA lists, one of which must contain a single element. This applies to both Scatter (src_list_size=1) and Gather to Remote (dst_list_size=1) operations.

The source address for each DMA operation is an effective address formed by the sum of src_addr and the offset specified in each DMA list element. The assumption is that all of the source data is in a contiguous buffer starting at src_addr. For cases where the source data may not be in a contiguous buffer with a known base address, a source address of zero may be specified. In this case the actual address of the data can be used as the offset in the DMA list element.
This is an asynchronous service in that the data transfers are only initiated (but not completed) when it returns. To ensure completion of the transfer on this DE you must make a call to dacs_wait() or dacs_test() with the same wait identifier. This ensures that the local buffers and transfer list parameter can be changed or reused.

The target remote memory region must have been previously accepted by the caller with a call to dacs_remote_mem_accept().

**dacs_put_list - Scatter (src_list_size = 1 dst_list_size = 4)**

![Diagram of dacs_put_list - Scatter](image)

**Dacs_put_list - Gather to Remote (src_list_size = 4 dst_list_size = 1)**

![Diagram of Dacs_put_list - Gather to Remote](image)

Put list to a remote memory region with src_list_size = 1
RETURN VALUE

The dacs_put_list service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_BUF_OVERFLOW**: the buffer has overflowed - the specified offset or size of one or more list elements exceed the bounds of the target buffer.
- **DACS_ERR_NOT_ALIGNED**: the buffer is not aligned correctly for the size of the transfer.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_ATTR**: the flag or enumerated constant is invalid.
- **DACS_ERR_INVALID_SIZE**: the size is zero or not supported by the platform.
- **DACS_ERR_INVALID_WID**: the wait identifier is invalid.
- **DACS_ERR_INVALID_HANDLE**: the remote memory handle is invalid.
- **DACS_ERR_NO_RESOURCE**: unable to allocate required resources.
- **DACS_ERR_NO_PERM**: the resource attributes do not allow this operation.

SEE ALSO

[dacs_put(3)  dacs_get(3)  dacs_get_list(3)  dacs_test(3)  dacs_wait(3) ]
NAME

dacs_get_list - Get data from a remote memory area and place it in local buffers.

SYNOPSIS

DACS_ERR_T dacs_get_list ( void *dst_addr, dacs_dma_list_t *dst_dma_list,
uint32_t dst_list_size, dacs_remote_mem_t src_remote_mem, dacs_dma_list_t *
src_dma_list, uint32_t src_list_size, dacs_wid_t wid, DACS_ORDER_ATTR_T
order_attr, DACS_BYTE_SWAP_T swap )

Call parameters
*dst_addr A pointer to the base address of the destination memory
    buffer.
*dst_dma_list A pointer to a list of entries describing transfer locations in the
    destination buffer.
dst_list_size The number of elements in the destination DMA list.
src_remote_mem A handle for the remote source memory buffer.
*src_dma_list A pointer to a list of entries describing transfer locations in the
    source buffer.
src_list_size The number of elements in the source DMA list.
wid The communication wait identifier associated with this
    transfer.
order_attr Ordering attribute. Possible values are:
    • DACS_ORDER_ATTR_FENCE: execution of this operation is
      delayed until all previously issued DMA operations to the
      same DE using the same wid have completed.
    • DACS_ORDER_ATTR_BARRIER: execution of this operation and all
      subsequent DMA operations are delayed until all previously
      issued DMA operations to the same DE using the same wid
      have been completed.
    • DACS_ORDER_ATTR_NONE: no ordering is enforced.
swap The little-endian or big-endian byte-swapping flag. Possible
    values are:
    • DACS_BYTE_SWAP_DISABLE,
    • DACS_BYTE_SWAP_HALF_WORD,
    • DACS_BYTE_SWAP_WORD or
    • DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

DESCRIPTION

The dacs_get_list service gets data from the remote memory area referenced
by the dst_remote_mem struct, using the specified dma_list, and places it in the buffers
specified by dst_dma_list. The interface supports the specification of two DMA
lists, one of which must contain a single element. This applies to both Gather
(dst_list_size=1) and Scatter to local (src_list_size=1) operations.

The destination address for each DMA operation is an effective address formed by
the sum of dst_addr and the offset specified in each DMA list element. The
assumption is that the destination buffers for the data are all within a contiguous
buffer starting at dst_addr. For cases where the destination buffers may not be in a
contiguous buffer with a known base address, a destination address of zero may
be specified. In this case the actual address of the destination buffer can be used as
the offset in the DMA list element.

This is an asynchronous service in that the data transfers are only initiated (but not completed) when it returns. To ensure completion of the transfer you should make a call to dacs_wait() or dacs_test() passing the wait identifier.

The target remote memory region must have been previously accepted by the caller with a call to dacs_remote_mem_accept().

**dacs_get_list - Gather (src_list_size = 4 dst_list_size = 1)**

![Diagram of dacs_get_list - Gather](image)

Get list from a remote memory region with source list size = 1
RETURN VALUE

The dacs_get_list service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_BUF_OVERFLOW: the buffer has overflowed - the specified offset or size of one or more list elements exceed the bounds of the target buffer.
- DACS_ERR_NOTAligned: the buffer is not aligned correctly for the size of the transfer.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_ATTR: the flag or enumerated constant is invalid.
- DACS_ERR_INVALID_SIZE: the size is zero or not supported by the platform.
- DACS_ERR_INVALID_WID: the wait identifier is invalid.
- DACS_ERR_INVALID_HANDLE: the remote memory handle is invalid.
- DACS_ERR_NO_RESOURCE: unable to allocate required resources.
- DACS_ERR_NO_PERM: the resource attributes do not allow this operation.

dacs_put(3), dacs_get(3), dacs_put_list(3), dacs_test(3), dacs_wait(3)

Message passing

The messaging passing services provide two way communications using the familiar send/recv model. These services are asynchronous, but can be synchronized using the dacs_test() and dacs_wait() services as needed.
**dacs_send**

**NAME**

dacs_send - send a message to another process

**SYNOPSIS**

```c
DACS_ERR_T dacs_send ( void *src_data, uint32_t size, de_id_t dst_de, dacs_process_id_t dst_pid, uint32_t stream, dacs_wid_t wid, DACS_BYTE_SWAP_T swap )
```

**Call parameters**

- `*src_data` - A pointer to the beginning of the source (send) message buffer.
- `size` - The size of the message buffer.
- `dst_de` - The message destination DE.
- `dst_pid` - The message destination process.
- `stream` - The identifier of the stream on which the message is to be sent.
- `wid` - A wait identifier.
- `swap` - The little-endian or big-endian byte-swapping flag. Possible values are:
  - DACS_BYTE_SWAP_DISABLE,
  - DACS_BYTE_SWAP_HALF_WORD,
  - DACS_BYTE_SWAP_WORD or
  - DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

**DESCRIPTION**

The dacs_send service asynchronously sends a message to another process. Upon successful return a send operation is either pending or in progress. Use dacs_test() or dacs_wait() to test for completion on this DE, so that the local buffer can be reused or changed.

**Note:** The size of the buffer at the destination process must be greater than or equal to amount of data sent; otherwise the send operation fails silently. This error will later be reported by dacs_test() or dacs_wait() as DACS_ERR_BUF_OVERFLOW.

**RETURN VALUE**

The dacs_send service returns an error indicator defined as:

- **DACS_SUCCESS:** normal return.
- **DACS_ERR_INVALID_ADDR:** the pointer is invalid.
- **DACS_ERR_INVALID_ATTR:** the flag or enumerated constant is invalid.
- **DACS_ERR_NO_RESOURCE:** unable to allocate required resources.
- **DACS_ERR_INVALID_DE:** the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID:** the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET:** this operation is not allowed for the target process.
- **DACS_ERR_NOT_ALIGNED:** the requested data transfer does not have proper alignment for its size.
- **DACS_ERR_INVALID_SIZE:** the size is zero or not supported by the platform.
- **DACS_ERR_INVALID_WID:** the wait identifier is invalid.
- **DACS_ERR_INVALID_STREAM:** the stream identifier is invalid.
SEE ALSO

dacs_recv(3), dacs_wait(3), dacs_test(3)

dacs_recv

NAME

dacs_recv - receive a message from another process

SYNOPSIS

DACS_ERR_T dacs_recv ( void *dst_data, uint32_t size, de_id_t src_de,
       dacs_process_id_t src_pid, uint32_t stream, dacs_wid_t wid,
       DACS_BYTE_SWAP_T swap )

Call parameters

*dst_data A pointer to the beginning of the destination (receive) data buffer.
size The size of the message buffer.
src_de The message source DE.
src_pid The message source process.
stream The stream on which to receive the message, or DACS_STREAM_ALL.
wid A wait identifier.
swap The little-endian or big-endian byte-swapping flag. Possible values are:
    • DACS_BYTE_SWAP_DISABLE,
    • DACS_BYTE_SWAP_HALF_WORD,
    • DACS_BYTE_SWAP_WORD or
    • DACS_BYTE_SWAP_DOUBLE_WORD.

See Chapter 9, “Data communication,” on page 39 for details.

Return parameter

*dst_data The pointer to the received data buffer.

DESCRIPTION

The dacs_recv service asynchronously receives a message from another process.
Upon successful return a receive operation is either pending or in progress. You
should use dacs_test() or dacs_wait() to test for completion.

The number of bytes sent by the source process must be less than or equal to the
local buffer size, otherwise the receive operation fails.

Stream identifiers are used to select messages for reception. A message will be
received if the stream identifier of the message matches the stream identifier
specified to dacs_recv(), or if DACS_STREAM_ALL is specified. Stream identifier
values must be between 0 and DACS_STREAM_UB inclusive.

The swap flag must be the same at both ends of the transfer. If not the completion
test (dacs_test() or dacs_wait()) will fail with DACS_ERR_BYTESWAP_MISMATCH, and
no data is transferred.
**RETURN VALUE**

The dacs_recv service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_ATTR**: the flag or enumerated constant is invalid.
- **DACS_ERR_NO_RESOURCE**: unable to allocate required resources.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET**: this operation is not allowed for the target process.
- **DACS_ERR_NOT_ALIGNED**: the buffer is not aligned properly for the size of the transfer.
- **DACS_ERR_INVALID_SIZE**: the size is zero or not supported by the platform.
- **DACS_ERR_INVALID_WID**: the wait identifier is invalid.
- **DACS_ERR_INVALID_STREAM**: the stream identifier is invalid.

---

**Mailboxes**

The mailbox services provide a simple method of passing a single 32-bit unsigned word between processes. These services use a blocking read/write model. The mailbox is a FIFO queue with an implementation-specific depth.

Mailboxes are between a host (parent) and an accelerator process (DE id and Pid). Each mailbox has two sets of slots. One set is written to by the host and read by the accelerator process, and the other is written to by the accelerator process and read by the host. A host with a single accelerator running a single process will have one mailbox with 32 slots in each set. A host with two accelerators, each running a single process, will have two mailboxes each with 32 slots in each set. Thus the host will have 32 slots in one mailbox for mail coming from one accelerator process and 32 slots in another mailbox for mail coming from the other accelerator process.

**Note:** Byte-swapping is done automatically if required. A DE cannot write to its own mailbox and can only read from its own mailbox. Any attempt to do otherwise returns an error.

For hybrid the mailbox depth is on a per child process basis, and the values are 32 (host) and 32 (accelerator); each accelerator process has 32/32.
dacs_mailbox_write

NAME

dacs_mailbox_write - Send a single variable to another process.

SYNOPSIS

DACS_ERR_T dacs_mailbox_write ( uint32_t *msg, de_id_t dst_de,
                              dacs_process_id_t dst_pid)

Call parameters
*msg A pointer to the message to write.
dst_de The message destination DE.
dst_pid The destination process id.

DESCRIPTION

The dacs_mailbox_write service writes a single 32-bit unsigned integer to
the specified target mailbox. There are an number of mailbox slots for each
process; this number is defined by the implementation. If the destination has an
empty mailbox slot this service returns immediately. Otherwise this service blocks until a
slot becomes available.

RETURN VALUE

The dacs_mailbox_write service returns an error indicator defined as:
• DACS_SUCCESS: normal return.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
• DACS_ERR_INVALID_PID: the specified PID does not refer to an active process.
• DACS_ERR_INVALID_TARGET: this operation is not allowed for the target process.

SEE ALSO

dacs_mailbox_read(3)  dacs_mailbox_test(3)
**dacs_mailbox_read**

**NAME**

dacs_mailbox_read - Receive a single variable from another process.

**SYNOPSIS**

```c
DACS_ERR_T dacs_mailbox_read ( uint32_t *msg, de_id_t src_de, dacs_process_id_t src_pid )
```

Call parameters

- `src_de` The message source DE.
- `src_pid` The message source process.

Return parameter

- `*msg` A pointer to the message received.

**DESCRIPTION**

The `dacs_mailbox_read` service reads a single 32-bit unsigned integer from the specified source mailbox. There are a number of mailbox slots for each process; this number is defined by the implementation. If the source does not have any pending mailbox messages this service call blocks until one arrives.

**RETURN VALUE**

The `dacs_mailbox_read` service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET**: operation not allowed for the target process.

**SEE ALSO**

- [dacs_mailbox_write(3)]
- [dacs_mailbox_test(3)]
**NAME**

dacs_mailbox_test - Test if a mailbox access will succeed.

**SYNOPSIS**

```c
DACS_ERR_T dacs_mailbox_test (DACS_TEST_MAILBOX_T rw_flag, de_id_t de, dacs_process_id_t pid, int32_t *mbox_status)
```

*Call parameters*

- **rw_flag**: Flag to indicate which mailbox to test:
  - **DACS_TEST_MAILBOX_READ**: test the read mailbox to see if a call to `dacs_mailbox_read()` will block, or
  - **DACS_TEST_MAILBOX_WRITE**: test the write mailbox to see if a call to `dacs_mailbox_write()` will block.

- **de**: The DE owning the mailbox to test.
- **pid**: The process owning the mailbox to test

*Return parameter*

- ***mbox_status**: A pointer to the location where the mailbox status is returned. The contents are:
  - set to zero if the mailbox will block, or
  - set to non-zero if the mailbox will not block.

**DESCRIPTION**

The **dacs_mailbox_test** service allows the programmer to test if the mailbox will block before calling `dacs_mailbox_read()` or `dacs_mailbox_write()`.

**RETURN VALUE**

The **dacs_mailbox_test** service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_ATTR**: the flag or enumerated constant is invalid.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET**: this operation is not allowed for the target process.

**SEE ALSO**

- `dacs_mailbox_read(3)`
- `dacs_mailbox_write(3)`
Chapter 10. Wait identifier management services

These services are intended to manage wait identifiers (WIDs), which are used to synchronize data communication. A WID is required for the data communication services, and is used to test for completion of asynchronous data transfers.

dacs_wid_reserve

NAME

dacs_wid_reserve - Reserve a wait identifier.

SYNOPSIS

DACS_ERR_T dacs_wid_reserve ( dacs_wid_t *wid )

Return parameter

*wid A pointer to the reserved wait identifier.

DESCRIPTION

The dacs_wid_reserve service reserves a wait identifier.

RETURN VALUE

The dacs_wid_release service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_NO_WIDS: no wait identifiers are available.

SEE ALSO

[ dacs_wid_release(3) ]
dacs_wid_release

NAME

dacs_wid_release - Release a reserved wait identifier.

SYNOPSIS

DACS_ERR_T dacs_wid_release ( dacs_wid_t *wid )

Call parameter

*wid A pointer to the wait identifier to be released.

DESCRIPTION

The dacs_wid_release service releases the reserved wait identifier. If a data transfer using the wait identifier is still active, an error is returned and the wait identifier is not released.

RETURN VALUE

The dacs_wid_release service returns an error indicator defined as:

- DACS_SUCCESS: normal return; the wait identifier was invalidated.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_WID_ACTIVE: a data transfer involving the wait identifier is still active.
- DACS_ERR_INVALID_WID: the specified wait identifier is not reserved.

SEE ALSO

[dacs_wid_reserve(3)]
Chapter 11. Transfer completion

A wait identifier is reserved and assigned to a data communication operation when it is started. These routines test the wait identifier to see if the communication operation has completed.

dacs_test

NAME

dacs_test - Test if communication operations have finished on this DE so the parameters can be changed or reused.

SYNOPSIS

DACS_ERR_T dacs_test( dacs_wid_t wid )

Call parameter

wid A communication wait identifier

DESCRIPTION

The dacs_test service checks the data transfers for the given communication wait identifier and returns their status.

RETURN VALUE

The dacs_test service returns an error indicator defined as:

- DACS_WID_READY: all data transfers have completed.
- DACS_WID_BUSY: one or more data transfers have not completed.
- DACS_WID_NOT_ACTIVE: there are no outstanding transfers to test.
- DACS_ERR_INVALID_WID: the specified wait identifier is invalid.
- DACS_ERR_BYTESWAP_MISMATCH: the Little-endian / Big-endian architectures at the ends of the transfer are incompatible.
- DACS_ERR_BUF_OVERFLOW: the data to be transferred is too large for the receive buffer.

SEE ALSO

[dacs_wait(3) dacs_put(3) dacs_get(3) dacs_put_list(3) dacs_get_list(3)]
**dacs_wait**

**NAME**

dacs_wait - Wait for a communications operation to finish. Wait for communication operations to finish on this DE so the parameters can be changed or reused.

**SYNOPSIS**

```c
DACS_ERR_T dacs_wait ( dacs_wid_t wid )
```

Call parameter

* wid A communication wait identifier

**DESCRIPTION**

The `dacs_wait` service blocks the caller, waiting for outstanding data transfers for the given wait identifier to complete. It returns when all outstanding transfers are finished. If one or more of the transfers fails, the first failure encountered is reported.

**RETURN VALUE**

The `dacs_wait` service returns an error indicator defined as:

- `DACS_WID_READY`: all data transfers have completed.
- `DACS_WID_NOT_ACTIVE`: there are no outstanding transfers to test.
- `DACS_ERR_INVALID_WID`: the specified wait identifier is invalid.
- `DACS_ERR_BYTESWAP_MISMATCH`: the Little-endian / Big-endian architectures at the ends of the transfer are incompatible.
- `DACS_ERR_BUF_OVERFLOW`: the data to be transferred is too large for the receive buffer.

Chapter 12. Locking Primitives

Shared data accesses can be serialized with DaCS by using a mutual exclusion primitive (mutex) to protect critical sections. A mutex can be hosted on any DE memory space and can be local or remote relative to the process calling these services.

The significant features of a mutex are:
- the mutex is not recursive,
- it is held by a particular DE/PID and that DE/PID is the only one that can unlock it, and
- the lock is not thread based within the DE/PID. Any thread in the locking DE/PID can unlock the mutex.

Sharing Mutexes

When a mutex is created on a PPU, which is an AE for DaCS for Hybrid, and the PPU is also a host for DaCS on Cell, the mutex can be shared by the PPU with both the x86_64 (DaCS for Hybrid HE) and the SPU (DaCS for Cell HE). The mutex can then be used to synchronize processes across all three levels.

The services which process a mutex fall into two categories:

mutex management services, for managing the mutex shared resource, which include dacs_mutex_init(), dacs_mutex_share(), dacs_mutex_accept(), dacs_mutex_release() and dacs_mutex_destroy(), and

mutex locking services, for locking and unlocking a mutex, which include dacs_mutex_lock(), dacs_mutex_unlock() and dacs_mutex_try_lock().
NAME
dacs_mutex_init - Initialize a mutual exclusion variable.

SYNOPSIS
DACS_ERR_T dacs_mutex_init ( dacs_mutex_t *mutex )

Return parameter
*mutex A pointer to a newly initialized mutex handle.

DESCRIPTION
The dacs_mutex_init service initializes a mutual exclusion variable and returns a handle to it.

RETURN VALUE
The dacs_mutex_init service returns an error indicator defined as:
  • DACS_SUCCESS: normal return.
  • DACS_ERR_INVALID_ADDR: the pointer is invalid.
  • DACS_ERR_NO_RESOURCE: unable to allocate required resources.

SEE ALSO
  dacs_mutex_share(3), dacs_mutex_accept(3), dacs_mutex_lock(3),
  dacs_mutex_try_lock(3), dacs_mutex_unlock(3), dacs_mutex_release(3),
  dacs_mutex_destroy(3)
NAME

dacs_mutex_share - Share a mutual exclusion variable with a remote process.

SYNOPSIS

DACS_ERR_T dacs_mutex_share ( de_id_t dst_de, dacs_process_id_t dst_pid, 
dacs_mutex_t mutex )

Call parameters

dst_de The target DE for the share.
dst_pid The target process for the share.
mutex The handle of the mutex that is to be shared.

DESCRIPTION

The dacs_mutex_share service shares the specified mutual exclusion variable
between the current process and the remote process specified by dst_de and
dst_pid. This service blocks the caller, waiting for the remote process to call
dacs_mutex_accept() to accept the mutex.

RETURN VALUE

The dacs_mutex_share service returns an error indicator defined as:

- DACS_SUCCESS: normal return; sharing succeeded.
- DACS_ERR_INVALID_DE: the specified DE is either invalid or not reserved.
- DACS_ERR_PID: the specified PID does not refer to an active process.
- DACS_ERR_TARGET: this operation is not allowed for the target process.
- DACS_ERR_HANDLE: the specified mutex handle is not valid.

**NAME**
dacs_mutex_accept - Receive a share on a mutual exclusion variable from a remote process.

**SYNOPSIS**

```
DACS_ERR_T dacs_mutex_accept ( de_id_t src_de, dacs_process_id_t src_pid, 
dacs_mutex_t *mutex )
```

**Call parameters**

- **src_de**: The source DE which is sharing the mutex handle.
- **src_pid**: The source PID which is sharing the mutex handle.

**Return parameter**

- ***mutex**: A pointer to the handle of the accepted mutex.

**DESCRIPTION**

The dacs_mutex_accept service receives a mutual exclusion variable from a remote process. The service blocks until the remote process shares the mutex with a call to dacs_mutex_share().

**RETURN VALUE**

The dacs_mutex_accept service returns an error indicator defined as:

- **DACS_SUCCESS**: normal return.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.
- **DACS_ERR_INVALID_DE**: the specified DE is either invalid or not reserved.
- **DACS_ERR_INVALID_PID**: the specified PID does not refer to an active process.
- **DACS_ERR_INVALID_TARGET**: this operation is not allowed for the target process.

dacs_mutex_lock(3), dacs_mutex_unlock(3), dacs_mutex_destroy(3)
dacs_mutex_lock

NAME

dacs_mutex_lock - Acquire a lock on a mutual exclusion variable.

SYNOPSIS

DACS_ERR_T dacs_mutex_lock ( dacs_mutex_t mutex )

Call parameter
mutex The handle of the mutex to lock.

DESCRIPTION

The dacs_mutex_lock service acquires the specified mutex. The caller must either be the owner of the mutex, or have previously accepted the mutex with a call to dacs_mutex_accept(). This service blocks the caller until the mutex is acquired.

RETURN VALUE

The dacs_mutex_lock service returns an error indicator defined as:
• DACS_SUCCESS: normal return; lock succeeded.
• DACS_ERR_INVALID_HANDLE: the specified mutex handle is not valid.

SEE ALSO

dacs_mutex_try_lock(3) dacs_mutex_unlock(3) dacs_mutex_release(3)
dacs_mutex_destroy(3)
dacs_mutex_try_lock

NAME

dacs_mutex_try_lock - Attempt to acquire a lock on a mutual exclusion variable.

SYNOPSIS

DACS_ERR_T dacs_mutex_try_lock ( dacs_mutex_t mutex )

Call parameter

mutex The handle of the mutex to lock.

DESCRIPTION

The dacs_mutex_try_lock service attempts to acquire a lock on a mutex. The caller must either be the owner of the mutex, or have previously accepted the mutex with a call to dacs_mutex_accept(). If the mutex is available for locking, this service gets the lock and returns. If a lock on the mutex is not available, this method returns with a DACS_ERR_MUTEX_BUSY status.

RETURN VALUE

The dacs_mutex_try_lock service returns an error indicator defined as:

- DACS_SUCCESS: normal return; lock was acquired.
- DACS_ERR_MUTEX_BUSY: the mutex is not available.
- DACS_ERR_INVALID_HANDLE: the specified mutex handle is not valid.

SEE ALSO

**dacs_mutex_unlock**

**NAME**

`dacs_mutex_unlock` - Unlock a mutual exclusion variable.

**SYNOPSIS**

```c
DACS_ERR_T dacs_mutex_unlock ( dacs_mutex_t mutex )
```

Call parameter

`mutex` The handle of the mutex to unlock.

**DESCRIPTION**

The `dacs_mutex_unlock` service unlocks a mutex. The caller must either be the owner of the mutex, or have previously accepted the mutex with a call to `dacs_mutex_accept()`.

**RETURN VALUE**

The `dacs_mutex_unlock` service returns an error indicator defined as:

- `DACS_SUCCESS`: normal return; unlock succeeded.
- `DACS_ERR_INVALID_HANDLE`: the specified mutex handle is not valid.

**SEE ALSO**

- `dacs_mutex_init(3)`, `dacs_mutex_share(3)`, `dacs_mutex_accept(3)`

- `dacs_mutex_destroy(3)`
**NAME**

dacs_mutex_release - Release a mutual exclusion variable.

**SYNOPSIS**

DACS_ERR_T dacs_mutex_release ( dacs_mutex_t *mutex )

Call parameter

*mutex A pointer to the handle of the mutex to release.

**DESCRIPTION**

The dacs_mutex_release service releases a previously accepted mutex object and invalidates the handle. When all accepters have released the mutex, it may be destroyed by its owner. This service does not block.

The release will succeed whether or not the mutex is held by the caller.

**RETURN VALUE**

The dacs_mutex_release service returns an error indicator defined as:

- DACS_SUCCESS: normal return.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.
- DACS_ERR_INVALID_HANDLE: the specified mutex handle is invalid.
- DACS_ERR_OWNER: this operation is not allowed for the owner of the resource.

**SEE ALSO**

dacs_mutex_destroy

NAME

dacs_mutex_destroy - Destroy a mutual exclusion variable.

SYNOPSIS

DACS_ERR_T dacs_mutex_destroy ( dacs_mutex_t *mutex )

Call parameter
mutex        A pointer to the handle of the mutex to destroy.

DESCRIPTION

The dacs_mutex_destroy service destroys the specified mutex and invalidates the
handle. This service blocks until all users of the mutex have released it. The mutex
may only be destroyed by the process that initialized it (the owner).

The destroy will succeed whether or not the mutex is held by its owner.

RETURN VALUE

The dacs_mutex_destroy service returns an error indicator defined as:
• DACS_SUCCESS: normal return.
• DACS_ERR_INVALID_ADDR: the pointer is invalid.
• DACS_ERR_INVALID_HANDLE: the specified mutex handle is invalid.
• DACS_ERR_NOT_OWNER: this operation is only valid for the owner of the resource.

Chapter 13. Error handling

DaCS provides support for registration of user-created error handlers which are called under certain error conditions. The error handlers can be called for synchronous or asynchronous errors.

In SDK 3.0 any synchronous error reported to the error handlers will cause the process to abort. This will happen when DaCS has detected a fatal error from which it cannot recover. Asynchronous errors include child failures (host process) and termination requests from a parent (accelerator process). Abnormal child termination will cause the parent to abort after calling all registered error handlers.

A normal child exit with a non-zero status will be reported asynchronously to the error handlers, but will not cause the process to abort. This allows the parent process to determine if the non-zero exit represents an error condition.

When it is called a user error handler is passed an error object describing the error, which can be inspected using services provided. The error object contains the DE and PID of the failing process. These can be used to call dacs_de_test() to reap its status and so allow another process to be started on that DE.

The DaCS library uses the SIGTERM signal for handling asynchronous errors and termination requests. A dedicated error handling thread is created in dacs_runtime_init() for this purpose. Applications using the DaCS library should not create any application threads before calling dacs_runtime_init(), and no application thread should unmask this signal.

User error handler example

User error handler registration

For this example we’re going to create an user error handler called my_errhandler. Once this has been defined we can register the user error handler using the dacs_errhandler_reg API:

dacs_rc= dacs_errhandler_reg((dacs_error_handler_t)&my_errhandler,0);

Note: If the address of my_errhandler is not passed or the cast to dacs_error_handler_t is omitted the compiler will produce warnings.

User error handler code:

```c
int my_errhandler(dacs_error_t error)
{
    /*need local variables for passback of values*/
    DACS_ERR_T dacs_rc=0;
    DACS_ERR_T dacs_error_rc;//hold code for error
    de_id_t de=0;
    dacs_process_id_t pid=0;
    uint32_t code = 0;
    const char * error_string;

    /* Get the DACS_ERR_T in the error to learn what happened */
```
printf("\n\n--in my_dacs_errhandler\n");  
dacs_error_rc=dacs_rc=dacs_error_num(error);  
printf(" dacs_error_num indicates DACS_ERR_T=%d %s\n",  
dacs_rc,dacs_strerror(dacs_rc));  
/* Get the exit code in the error to learn what happened */  
dacs_rc=dacs_error_code(error,&code);  
if(dacs_rc){ //if error invoking dacs_error_code  
  printf(" dacs_error_code call had error DACS_ERR_T=%d %s\n",  
             dacs_rc,dacs_strerror(dacs_rc));  
} else {  
  if (DACS_STS_PROC_ABORTED==dacs_error_rc){  
    printf(" dacs_error_code signal signal=%d \n",code);  
  } else if (DACS_STS_PROC_FAILED==dacs_error_rc){  
    printf(" dacs_error_code exit code=%d\n",code);  
  } else { //else reason is different than aborted or failed  
    printf(" dacs_error_code exit/signal code=%d\n",code);  
  }  
}  
/* Get the error string in the error to learn what happened */  
dacs_rc=dacs_error_str(error,&error_string);  
if(dacs_rc){ //if error invoking dacs_error_str  
  printf(" dacs_error_str call had error DACS_ERR_T=%d %s\n",  
             dacs_rc,dacs_strerror(dacs_rc));  
} else {  
  printf(" dacs_error_str=%s\n",error_string);  
}  
/* what DE had this error ? */  
dacs_rc=dacs_error_de(error,&de);  
if(dacs_rc){ //if error invoking dacs_error_de  
  printf(" dacs_error_de call had error DACS_ERR_T=%d %s\n",  
             dacs_rc,dacs_strerror(dacs_rc));  
} else {  
  printf(" dacs_error_de=01020200\n",de);  
}  
/* what was the dacs_process_id_t? */  
dacs_rc=dacs_error_pid(error,&pid);  
if(dacs_rc){ //if error invoking dacs_error_pid  
  printf(" dacs_error_pid call had error "  
                    "DACS_ERR_T=%d %s\n",dacs_rc,dacs_strerror(dacs_rc));  
} else {  
  printf(" dacs_error_pid=%ld\n",pid);  
}  
printf("exiting user error handler\n\n");  
return 0; //in SDK 3.0, return value is ignored

User error handler output

Example output if the accelerator program exits with a return code of 9:

--in my_dacs_errhandler
 dacs_error_num indicates DACS_ERR_T=4 DACS_STS_PROC_FAILED
 dacs_error_code exit code=9
 dacs_error_code=9
 dacs_error_str=DACS_STS_PROC_FAILED
 dacs_error_de=01020200
 dacs_error_pid=5503
exiting user error handler
Example output if the accelerator program aborts:

```
    -- in my_dacs_errhandler
    dacs_error_num = 5  DACS_STS_PROC_ABORTED
    dacs_error_code = 6  DACS_STS_PROC_ABORTED
    dacs_error_de = 01020200
    dacs_error_pid = 5894
    exiting user error handler
```

### dacs_errhandler_reg

**NAME**

`dacs_errhandler_reg` - Register an error handler to be called when an asynchronous or fatal error occurs.

**SYNOPSIS**

```c
DACS_ERR_T dacs_errhandler_reg (dacs_error_handler_t handler, uint32_t flags)
```

**Call parameters**

- `handler`:
  A pointer to an error handling function. This function will be passed the error object containing the error information, and returns a boolean indicating whether termination is requested or not. For fatal internal errors the process will be terminated without consideration for the handler's return value.

- `flags`:
  Flags for error handling options.
  **Note:** In SDK 3.0 no flags are supported: the flags value passed in must be 0 (zero).

The prototype of the handler is:

```c
int (*dacs_error_handler_t) (dacs_error_t error)
```

The user-registered handler must accept a handle to an error object, and return 1 (one) or 0 (zero) to indicate whether the error is deemed fatal or not.

**DESCRIPTION**

The `dacs_errhandler_reg` service registers an error handler. This handler will then be called whenever an asynchronous DaCS process fails, or a synchronous DaCS process encounters a fatal error.

**Note:** In SDK 3.0 the return value from the user handler will be ignored in all cases.

**Note:** If the error handler is coded in the form

```c
int my_errhandler(dacs_error_t error)
```

then write the registration as

```c
dacs_rc=dacs_errhandler_reg((dacs_error_handler_t)&my_errhandler,0);
```

where `dacs_rc` has been declared as a variable of type `DACS_ERROR_T`.

Chapter 13. Error handling  79
**RETURN VALUE**

The `dacs_errhandler_reg` service returns an error indicator defined as:
- `DACS_SUCCESS`: normal return.
- `DACS_ERR_INVALID_ADDR`: the pointer is invalid.
- `DACS_ERR_INVALID_ATTR`: the flag or enumerated constant is invalid.
- `DACS_ERR_NO_RESOURCE`: unable to allocate required resources.

**SEE ALSO**

`dacs_strerror(3)`, `dacs_error_num(3)`, `dacs_error_code(3)`, `dacs_error_str(3)`, `dacs_error_de(3)`, `dacs_error_pid(3)`

---

**dacs_strerror**

**NAME**

`dacs_strerror` - Return a pointer to a string describing an error.

**SYNOPSIS**

```c
const char * dacs_strerror ( DACS_ERR_T errcode )
```

**DESCRIPTION**

The `dacs_strerror` service returns a pointer to the error string for the given error code. The input error code can be any error returned by the DaCS API.

**RETURN VALUE**

The `dacs_strerror` service returns the error string for the given error code, or NULL if no string was found.

**SEE ALSO**

`dacs_strerror(3)`, `dacs_error_num(3)`, `dacs_error_code(3)`, `dacs_error_str(3)`, `dacs_error_de(3)`, `dacs_error_pid(3)`
**dacs_error_num**

**NAME**

dacs_error_num - Return the error code for the specified error handle.

**SYNOPSIS**

DACS_ERR_T dacs_error_num ( dacs_error_t error )

Call parameter
error An error handle.

**DESCRIPTION**

The dacs_error_num service returns the error code associated with the specified error handle.

**RETURN VALUE**

The dacs_error_num service returns a DaCS error code, or
DACS_ERR_INVALID_HANDLE if the given handle does not refer to a valid error object.

**SEE ALSO**

dacs_errhandler_reg(3), dacs_strerror(3), dacs_error_code(3), dacs_error_str(3), dacs_error_de(3), dacs_error_pid(3)
**dacs_error_code**

**NAME**

dacs_error_code - Retrieve the extended error code from the specified error object.

**SYNOPSIS**

DACS_ERR_T dacs_error_code ( dacs_error_t error , uint32_t *code )

Call parameter
error  An error handle.

Return parameter
*code  A pointer to the error code.

**DESCRIPTION**

The dacs_error_code service retrieves the platform-specific extended error code from the specified error object.

**RETURN VALUE**

The dacs_error_code service returns an error indicator defined as:
- DACS_SUCCESS: normal return; error code is returned in code.
- DACS_ERR_INVALID_HANDLE: the error handle is invalid.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.

**SEE ALSO**

dacs_errhandler_reg(3)  dacs_strerror(3)  dacs_error_num(3)  dacs_error_str(3)  
dacs_error_de(3)  dacs_error_pid(3)
**NAME**

dacs_error_str - Retrieve the error string for the specified error object.

**SYNOPSIS**

DACS_ERR_T dacs_error_str ( dacs_error_t error, const char **errstr )

Call parameter
error          An error handle.

Return parameter
**errstr       A pointer to the error string.

**DESCRIPTION**

The dacs_error_str service returns the error string associated with the specified error. This is the string that is returned from dacs_strerror().

**RETURN VALUE**

The dacs_error_str service returns an error indicator defined as:
- DACS_SUCCESS: normal return: a pointer to the error string is passed back in errstr.
- DACS_ERR_INVALID_HANDLE: the specified error handle is invalid.
- DACS_ERR_INVALID_ADDR: the pointer is invalid.

**SEE ALSO**

[ dacs_errhandler_reg(3) ] [ dacs_strerror(3) ] [ dacs_error_num(3) ] [ dacs_error_code(3) ]
[ dacs_error_de(3) ] [ dacs_error_pid(3) ]
**dacs_error_de**

**NAME**

dacs_error_de - Retrieve the originating DE for the specified error object.

**SYNOPSIS**

DACS_ERR_T dacs_error_de ( dacs_error_t error, de_id_t *de )

Call parameter
error                An error handle.

Return parameter
*de                  A pointer indicating the DE which was the source of the error.

**DESCRIPTION**

The dacs_error_de service returns the originating DE for the specified error object.

**RETURN VALUE**

The dacs_error_de service returns an error indicator defined as:
- **DACS_SUCCESS**: normal return: the originating DE is passed back in *de.
- **DACS_ERR_INVALID_HANDLE**: the specified error handle is invalid.
- **DACS_ERR_INVALID_ADDR**: the pointer is invalid.

**SEE ALSO**
dacs_errhandler_reg(3) dacs_strerror(3) dacs_error_num(3) dacs_error_code(3)
dacs_error_str(3) dacs_error_pid(3)
dacs_error_pid

NAME

dacs_error_pid - Retrieve the originating PID for the specified error object.

SYNOPSIS

DACS_ERR_T dacs_error_pid ( dacs_error_t error, dacs_process_id_t *pid )

Call parameter
error
An error handle.

Return parameter
*pid
A pointer indicating the PID which was the source of the error.

DESCRIPTION

The dacs_error_pid service returns the originating PID for the specified error object.

RETURN VALUE

The dacs_error_pid service returns an error indicator defined as:
- DACS_SUCCESS: normal return; the originating PID is passed back in pid.
- DACS_ERR_INVALID_HANDLE: the specified error handle is invalid.

SEE ALSO

dacs_errhandler_reg(3), dacs_strerror(3), dacs_error_num(3), dacs_error_code(3), dacs_error_str(3), dacs_error_de(3)
Appendix A. Data types

Data type declarations in this document follow the C99 (ISO/IEC 9899:1999) convention. In addition, the following data types are defined in dacs.h:

dacs_remote_mem_t
   A handle to a memory region specified for use by other remote processes

dacs_dma_list_t
   This structure describes a dma_list_element in 64 bit addressing mode
   • uint64_t offset: 64-bit offset into the dacs_remote_mem_t block
   • uint64_t size: size of the buffer to be transferred, in bytes

define  struct dma_list
{
   uint64_t_t offset;
   uint64_t size;
} dacs_dma_list_t;

dacs_error_t
   This is an opaque handle which refers to an error object. A handle of this type is passed to the user-registered handler.

int (*dacs_error_handler_t)( dacs_error_t error)
   The user-registered handler must accept a handle to an error object and return 1 or 0 to indicate whether the error is deemed fatal.
Appendix B. DaCS DE types

The current DaCS Element (DE) types in the current supported DaCS topology are listed below.

**DACS_DE_SYSTEMX**
The supervising host for a node.

**DACS_DE_CELL_BLADE**
An entire Cell BE blade. If a program is run on this DE, it has 16 SPE children, and the DACS_DE_CBE elements are not allowed to execute any processes. Some applications may find this configuration useful.

**DACS_DE_CBE**
Cell BE Blade Engine. A Cell BE Blade contains two of these. If used this way, a Cell BE has 8 SPE children. As with the DACS_DE_CELL_BLADE, if processes are running on a DACS_DE_CBE element, no processes are allowed on the parent DACS_DE_CELL_BLADE. Running processes on a Cell BE node allows finer control of memory and processor affinity and may increase performance.

**DACS_DE_SPE**
Cell BE Synergistic Processing Element.
Appendix C. DaCS debugging

This chapter explains some of the alternatives provided within the SDK to debug a Hybrid DaCS application. The standard methods of using GDB or printf can still be used, but these have some unique considerations. The Hybrid DaCS daemons, which manage the Hybrid DaCS processes, provide logs and methods of retaining runtime information, such as core dumps and the contents of the current working directory. Hybrid DaCS also provides three different versions of the library with different levels of error checking. The base version is optimized for performance and provides limited error checking and no tracing. The trace version provides tracing support and the debug version provides error checking (such as parameter verification on all the APIs).

printf considerations

The easiest and most well known way to debug a program is to add printf statements at strategic points. This method can be useful in hybrid application debug provided the developer understands the following considerations:

- printf output may be interleaved between host and accelerator application output, and may not be in exact time sequence order of invocation between the two (or more) applications running;
- DaCS buffers the stderr and stdout streams of the accelerator. The buffers are generally flushed when a newline character is introduced into the stream. Flushing the stream directly may have little or no impact on displaying the data because of this behavior.

Debugging with GDB

Even though a comprehensive debugger is not available, gdb and gdbserver may be used. However, for debugging applications on the PPU the two debuggers provided by the SDK, ppu-gdb and ppu-gdbserver, should be used. These debuggers provide the same options and capabilities as the normal gdb programs but are specifically targeted for the PPU architecture.

To debug a hybrid PPU application you have a number of options.

1. If the process is running, attach to the process and debug. The process id can be found by using executing ps -ef on the command line of the PPU:

   ppu-gdb <program name> <process id>

2. If the process is failing use one of the following techniques to attach the debugger to the process prior to the program ending:
   a. Use the facilities provided by DaCS to start a debugging session with ppu-gdbserver. In order to do this an environment variable needs to be set either prior to launching the host application or within the application.
   The DaCS_START_PARENT environment variable allows you to change the program that is launched on the PPU. Substitution variables can be used within the command:

   %e the accelerator executable name, and
   %a arguments to be passed to the executable.

   For example:
export DACS_START_PARENT="/usr/bin/ppu-gdbserver localhost:5678 %e %a"

Once the application is started the accelerator application will wait for a ppu-gdb client to connect to it. (This assumes that the debugging is being performed on the PPU client, and that the client source code is available on the PPU.) For example:

> ppu-gdb program
(gdb) target remote localhost:5678
(gdb) <debug as usual>

If debugging remotely, for example from an x86 client, it will be necessary to find the proper levels of code and library that are installed on the PPU for proper debugging. It will be easier to start by debugging directly on the PPU. Refer to the gdb documentation for setting the shared library and source code paths.

b. Add a sleep() call of long enough duration so that the debugger can be started up and attached to the process.

c. Include a global variable and strategic while loop in the code to halt the program so that gdb can be attached, for example:

Program:
```c
int gdbwait = 1;

int main(int argc, char* argv[])
{
    .
    while(gdbwait);
    .
}
```

Command line:
```bash
> ppu-gdb program 23423
(gdb) set gdbwait=0
(gdb) c
```

d. Include code to use sigwait to wait for the user to attach, setting the ACCEL_DEBUG_START environment variable for the host process and then passing it to the child using either dacs_runtime_init() or dacs_de_start() and its envp parameter, or set the the DACS_START_ENV_LIST environment variable

DACS_START_ENV_LIST="ACCEL_DEBUG_START=Y"

before running the host process. Once the remote process has started it waits until you attach to it using a debugger, for example ppu-gdb -p <pid>. If ACCEL_DEBUG_START is not set the process executes normally.

Example:
```c
#include <signal.h>
#include <syscall.h>
...
/*
In the case of ACCEL_DEBUG_START, actually wait until the user *has* attached a debugger to this thread. This is done here by doing an sigwait on the empty set, which will return with EINTR after the debugger has attached.
*/
if (.getenv("ACCEL_DEBUG_START")) {
    int my_pid = getpid();
    fprintf(stdout,"\nPPU64: ACCEL_DEBUG_START ... attach debugger to pid %d\n", my_pid);
    fflush(stdout); sigset_t_set; sigemptyset (&set);
```
Daemon Support

The Hybrid DaCS library has multiple daemons monitoring the running DaCS applications. The daemons log errors and informational messages to specific system logs. The daemons provide the capability of capturing core files that may be generated on catastrophic failure and may retain the current working directory on the accelerator for later examination. These are the main features that will be used when debugging applications, but the daemons support other configuration options which may be useful in debugging certain types of problems. These options are documented in the /etc/dacsd.conf file. The following sections discuss the main features listed above.

Logs

The Hybrid DaCS daemon logs may contain invaluable information for debugging problems. The logs are located in

- /var/log/hdacsd.log on the host, and
- /var/log/adacsd.log on the accelerator

by default. These locations may be overridden in the daemon configuration file located in /etc/dacsd.conf.

The logs require root authority to view.

The daemons support more detailed logging by setting the environment variable DACS_HYBRID_DEBUG=Y when launching the application. This variable will also be passed on to the accelerator daemon as well. The DACS_HYBRID_DEBUG environment variable increases the log level in hdacsd and adacsd for the duration of the application, and also creates a DaCSD SPI log for the HE and AE applications in the /tmp directory on the host and the accelerator. The log file names are /tmp/dacsd_spi_<pid>.log, where <pid> is the process id of the host or accelerator application.

Failures of a DaCS application often occur within the first few DaCS functions called. The logs may provide detailed information as to the reason of the failure. Some typical errors are:

- `dacs_runtime_init()` - failures during this call are usually related to incompatibilities between a Hybrid DaCS application and the daemons installed on the system. A message in the logs will indicate this failure:

```
SocketSrv   init: version mismatch
```

- `dacs_reserve_children()` - failures during this call can usually be tracked back to errors in the /etc/dacsd_topology.config file. The IP addresses and reservation visibility should be verified. For more information on the configuration file refer to the installation guide shipped with the SDK.

The actual number of accelerators allocated by this function may not match the number requested; in particular "zero" available accelerators may be returned with an empty DE list. This function does not return a failure if no accelerators are available. The user must check the return values of this function before proceeding.
dacs_de_start() - failures during this call are typically program and library path related issues.

- verify that the program name being passed is a full path name to the executable, and that the executable exists on the target if the creation flag passed is DACS_PROC_REMOTE_FILE, or on the local host if DACS_PROCESS_LOCAL_FILE.
- verify that the shared libraries can be found correctly on the accelerator. This may be done in several ways.
  - Use RPATH when linking the accelerator application, where the RPATH points to the exact location of the libraries on the accelerator.
  - Use LD_LIBRARY_PATH. Since a user’s profile is not set up when the accelerator application launches you must specify the LD_LIBRARY_PATH in the DACS_START_ENV_LIST environment variable to correctly find all of the libraries.
  - Use ldconfig on the accelerator to cache the proper location of the shared libraries.
  - Pass all of the libraries down with the accelerator application into the same working directory using the DACS_PROC_LOCAL_FILE_LIST creation flag and a file list that contains the absolute path of the program and each library needed to run.

Core files

The adacsd daemon has a configuration option to specify the generation of core files. The configuration file is found in /etc/dacsd.conf. The following is an excerpt of the relevant portion of this configuration file.

```plaintext
# Set curlimit on core dump resource limit for AE application.
# The curlimit is a soft limit and is less than the max limit,
# which is a hard limit.
# If a core dump is larger than the curlimit the dump will not occur.
# If child_rlimit_core=0, the current resource limit is NOT changed
# for the AE child
# if child_rlimit_core=value>0 the current resource limit will be
# changed to min(value, hard_limit).
# If child_rlimit_core=-1 the resource limit will be set to the hard
# limit--which could be infinite

child_rlimit_core=0
```

If this value is changed the daemon must re-read the configuration file as described below.

Saving to the CWD

The adacsd daemon configuration file also supports keeping the current working directory (CWD) after the process has executed on the accelerator. This can be specified in the /etc/dacsd.conf file. The relevant excerpt is shown below:

```plaintext
# Normally the AE Current Working Directory and its contents
# are deleted when the AE process terminates.
# Set ae.cwd.keep=true if you want to prevent the
# AE Current Working Directory from being deleted.

ae.cwd.keep=false
```

If this value is changed the daemon must re-read the configuration file as described below.
To find where the core file is being written, issue the command:

```
cat /proc/sys/kernel/core_pattern
```

If the result is `core` then the core file is written in the current working directory. Since the current working directory is by default removed on termination, core files will be lost without further changes. You are recommended to change this by:

```
echo "*/tmp/core-%t-%e.%p" > /proc/sys/kernel/core_pattern
```

which will write any core dumps into the `/tmp` directory with a name of `core-<timestamp>-<executable>.<pid>`.

**Making daemon configuration changes take effect**

On reboot the adacsd will re-read the configuration file and the changes will take effect. The changes can be made effective immediately by sending a SIGHUP signal to the adacsd daemon. For example, run these commands on the CBE platform command line:

```
> ps aux | grep adacsd # find the process ID
> kill -s SIGHUP <adacsd_process_ID>
```

The process ID may be found in the pidfile as well. See the line for ADACSD_ARGS in dacsd.conf:

```
ADACSD_ARGS="--log /var/log/adacsd.log --pidfile /var/run/adacsd.pid"
```

and `cat /var/run/adacsd.pid`

**DaCS library versions**

The optimized version of `libdacs_hybrid` is installed in `/opt/cell/sdk/prototype/usr/lib64` and will normally be used in production. Two other libraries are also available for development purposes; each library provides a different set of functionality to help in analyzing an application. To use a library temporarily `LD_LIBRARY_PATH` can be set in the local environment, and also on the accelerator by using the DACS_START_ENV_LIST environment variable. An example of this is:

```
export LD_LIBRARY_PATH=/opt/cell/sdk/prototype/usr/lib64/dacs/debug
export DACS_START_ENV="LD_LIBRARY_PATH=${LD_LIBRARY_PATH}"
```

**Note:** The other versions of the library must be installed on the accelerator, or the dacs_de_start() call will fail.

**Error Checking Library**

Hybrid DaCS provides an error checking library to enable additional error checking, such as validation of parameters on the DaCS APIs. The error checking library is found in directory `/opt/cell/sdk/prototype/usr/lib64/dacs/debug`.

It is recommended that this library is used when first developing a DaCS application. Once the application is running successfully the developer can then use the regular runtime library.

**Trace enabled Library**

Hybrid DaCS provides a tracing and debug library to track DaCS library calls. The trace library is found in directory `/opt/cell/sdk/prototype/usr/lib64/dacs/trace`.
Linking with this library instead of the production or debug library will provide additional traces that can be used to debug where a program is failing by seeing what calls are made, their arguments, and the return value associated with the call. Refer to the PDT users guide for additional capabilities of this library and environment.
Appendix D. Performance and debug trace

The Performance Debugging Tool (PDT) provides trace data necessary to debug functional and performance problems for applications using the DaCS library.

Versions of the DaCS libraries built with PDT trace hooks enabled are delivered with SDK 3.0.

Installing and running the PDT

The libraries with the trace hooks enabled are packaged in separate -trace named packages. The trace enabled libraries install to a subdirectory named dacs/trace in the library install directory. These packages and the PDT are included in the SDK 3.0 package but may not be installed by default. Please refer to the PDT user’s guide for full instructions on how to install PDT, and how to set the correct environment variables to cause trace events to be generated. Included in the DaCS trace package is an example PDT configuration file which shows the available trace events that can be enabled or disabled.

Trace control

In the hybrid environment, PDT functions the same as it does in the single-system environment: When a PDT-enabled application starts, PDT reads its configuration from a file. For a distributed DaCS application you can distribute the PDT configuration with each job by specifying it as one of the DACS_START_FILES (see “dacs_de_start” on page 22). The PDT configuration for DaCS is separate from the configuration for your job.

Environment variable

PDT supports an environment variable (PDT_CONFIG_FILE) which allows you to specify the relative or full path to a configuration file. DaCS will ship an example configuration file which lists all of the DaCS groups and events and allows you to turn selected items on or off as desired. This will be shipped as:

/usr/share/pdt/config/pdt_dacs_config_hybrid.xml

In order to see the trace events the application must be built with the trace-enabled libraries. To see SPE events the application’s SPE code must be rebuilt with special compile settings (see the PDT User’s Guide for specifics) and needs to be linked with /usr/spu/lib/dacs/trace/libdacs.a, the trace-enabled DaCS SPU library code. To see PPE events the application must use the trace-enabled DaCS PPU code. If the application is using the static PPU library then it must be re-linked with /usr/lib64/dacs/trace/libdacs.a, the trace-enabled DaCS PPU library code. If the application was built using the shared PPU library then no re-linking is needed. In that case the library path must be changed to point to the trace-enabled PPU code as well as the PDT trace library, by setting the environment before running the application:

LD_LIBRARY_PATH=/usr/lib64/dacs/trace:/usr/lib64/trace
Appendix E. DaCS trace events

Where inputs or outputs are pointers to scalar types, both the pointer and the contents will be traced. To avoid any extra overhead of checking for NULL pointers, the trace code will only trace contents for pointers that are either required to be non-NULL by the API spec. or already have appropriate checks in the library. The contents of aggregate types will not be traced unless the entire object is passed in as an argument.

In general, there will be two trace hooks per API. The first will trace the input parameters and the second will trace the output values as well as the time interval of the API call. The performance hooks will generally have entry and exit hooks so the post-processing tools can show the time deltas. Note that the performance hooks are also debug hooks and will be enabled when either category is enabled.

### DaCS performance hooks

The COUNTERS and TIMERS hooks contain data that are accumulated during the DaCS calls. These data and trace events are reported by the dacs_runtime_exit() function.

Appendix F. Error codes

This section describes the DaCS error codes

All error codes which may be issued by DaCS APIs are listed here:

**DACS_ERR_BUF_OVERFLOW**: Buffer overflow
- the specified offset or size exceed the bounds of the target buffer.

**DACS_ERR_BYTESWAP_MISMATCH**: The byte swap flags on the source and target do not match.

**DACS_ERR_DAOSD_FAILURE**: Unable to communicate with DaSD.
**DACS_ERR_GROUP_CLOSED**: The group is closed.
**DACS_ERR_GROUP_DUPLICATE**: The specified process is already a member of the specified group.
**DACS_ERR_GROUP_OPEN**: The group has not been closed.
**DACS_ERR_INITIALIZED**: DaCS is already initialized.

**DACS_ERR_INVALID_ARGV**: The value of argv is too large or invalid.
**DACS_ERR_INVALID_ADDR**: The pointer is invalid.
**DACS_ERR_INVALID_ATTR**: The flag or enumerated constant is invalid.
**DACS_ERR_INVALID_DE**: The specified DE is either invalid or not reserved.
**DACS_ERR_INVALID_ENV**: The value of env is too large or invalid.
**DACS_ERR_INVALID_HANDLE**: The handle is invalid.
**DACS_ERR_INVALID_PID**: The specified PID does not refer to a valid process.
**DACS_ERR_INVALID_PROG**: Unable to execute the specified program.
**DACS_ERR_INVALID_SIZE**: The size is zero or is not supported by the platform.
**DACS_ERR_INVALID_STREAM**: The stream identifier is invalid.
**DACS_ERR_INVALID_TARGET**: This operation is not allowed for the target DE or process.
**DACS_ERR_INVALID_WID**: The wait identifier is invalid.
**DACS_ERR_MUTEX_BUSY**: The mutex is not available.
**DACS_ERR_NO_PERM**: The process does not have the appropriate privilege or the resource attributes do not allow the operation.
**DACS_ERR_NO_RESOURCE**: Unable to allocate required resources.
**DACS_ERR_NO_WIDS**: No more wait identifiers are available to be reserved.
**DACS_ERR_NOT_ALIGNED**: The buffer is incorrectly aligned for the size of the data.
**DACS_ERR_NOT_INITIALIZED**: DaCS has not been initialized.
**DACS_ERR_NOT_OWNER**: This operation is only permitted for the owner of the resource.
**DACS_ERR_OWNER**: This operation is not permitted for the owner of the resource.
**DACS_ERR_PROC_LIMIT**: The maximum number of processes supported has been reached.
**DACS_ERR_PROHIBITED**: This operation is prohibited by the implementation.
**DACS_ERR_RESOURCE_BUSY**: The specified resource is in use.
**DACS_ERR_SYSTEM**: A system error was encountered.

This often indicates an executible file was not found on the remote system.
**DACS_ERR_VERSION_MISMATCH**: Version mismatch between library and DaSD.
**DACS_ERR_WID_ACTIVE**: A data transfer involving the wait identifier is still active.
**DACS_ERR_WID_NOT_ACTIVE**: There are no outstanding transfers to test.
**DACS_STS_PROC_ABORTED**: The process terminated abnormally.
**DACS_STS_PROC_FAILED**: The process exited with a failure.
**DACS_STS_PROC_FINISHED**: The process finished execution without error.
**DACS_STS_PROC_RUNNING**: The process is still running.
**DACS_SUCCESS**: The API returned successfully.
**DACS_WID_READY**: All data transfers have completed.
**DACS_WID_BUSY**: One or more data transfers have not completed.
**DACS_WID_NOT_ACTIVE**: There are no outstanding transfers to test.
Appendix G. Accessibility features

IBM® and accessibility

See the IBM Accessibility Center at [http://www.ibm.com/able/] for more information about the commitment that IBM has to accessibility.
Notices

This information was developed for products and services offered in the U.S.A.

The manufacturer may not offer the products, services, or features discussed in this document in other countries. Consult the manufacturer's representative for information on the products and services currently available in your area. Any reference to the manufacturer's product, program, or service is not intended to state or imply that only that product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any intellectual property right of the manufacturer may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any product, program, or service.

The manufacturer may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to the manufacturer.

For license inquiries regarding double-byte (DBCS) information, contact the Intellectual Property Department in your country or send inquiries, in writing, to the manufacturer.

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: THIS INFORMATION IS PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. The manufacturer may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to Web sites not owned by the manufacturer are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this product and use of those Web sites is at your own risk.

The manufacturer may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact the manufacturer.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.
The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, IBM License Agreement for Machine Code, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning products not produced by this manufacturer was obtained from the suppliers of those products, their published announcements or other publicly available sources. This manufacturer has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to products not produced by this manufacturer. Questions on the capabilities of products not produced by this manufacturer should be addressed to the suppliers of those products.

All statements regarding the manufacturer’s future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

The manufacturer’s prices shown are the manufacturer’s suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to the manufacturer, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. The manufacturer, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

CODE LICENSE AND DISCLAIMER INFORMATION:

The manufacturer grants you a nonexclusive copyright license to use all programming code examples from which you can generate similar function tailored to your own specific needs.

SUBJECT TO ANY STATUTORY WARRANTIES WHICH CANNOT BE EXCLUDED, THE MANUFACTURER, ITS PROGRAM DEVELOPERS AND SUPPLIERS, MAKE NO WARRANTIES OR CONDITIONS EITHER EXPRESS OR
IMPLIED, INCLUDING BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT, REGARDING THE PROGRAM OR TECHNICAL SUPPORT, IF ANY.

UNDER NO CIRCUMSTANCES IS THE MANUFACTURER, ITS PROGRAM DEVELOPERS OR SUPPLIERS LIABLE FOR ANY OF THE FOLLOWING, EVEN IF INFORMED OF THEIR POSSIBILITY:
1. LOSS OF, OR DAMAGE TO, DATA;
2. SPECIAL, INCIDENTAL, OR INDIRECT DAMAGES, OR FOR ANY ECONOMIC CONSEQUENTIAL DAMAGES; OR
3. LOST PROFITS, BUSINESS, REVENUE, GOODWILL, OR ANTICIPATED SAVINGS.

SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF DIRECT, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, SO SOME OR ALL OF THE ABOVE LIMITATIONS OR EXCLUSIONS MAY NOT APPLY TO YOU.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

  - Book III: PowerPC Operating Environment Architecture
Glossary

Accelerator
General or special purpose processing element in a hybrid system. An accelerator might have a multi-level architecture with both host elements and accelerator elements. An accelerator, as defined here, is a hierarchy with potentially multiple layers of hosts and accelerators. An accelerator element is always associated with one host. Aside from its direct host, an accelerator cannot communicate with other processing elements in the system. The memory subsystem of the accelerator can be viewed as distinct and independent from a host. This is referred to as the subordinate in a cluster collective.

de_id
A unique number assigned to the physical processing element in a topology. The de_id is usually assigned (or derived) when the node is powered up. It should not change until the node is powered down again.

group
A group construct specifies a collection of DaCS DEs and processes in a system.

handle
A handle is an abstraction of a data object; usually a pointer to a structure.

Host
A general purpose processing element in a hybrid system. A host can have multiple accelerators attached to it. This is often referred to as the master node in a cluster collective.

Hybrid
A 64 bit x86 system using a Cell BE as an accelerator.

Main thread
The main thread of the application. In many cases, Cell/B.E. architecture programs are multi-threaded using multiple SPEs running concurrently. A typical scenario is that the application consists of a main thread that creates as many SPE threads as needed and the application organizes them.

node
A node is a functional unit in the system topology, consisting of one host together with all the accelerators connected as children in the topology (this includes any children of accelerators).
**parent**
The parent of a DE is the DE that resides immediately above it in the topology tree.

**PPE**
PowerPC Processor Element. The general-purpose processor in the Cell/B.E. processor.

**process**
A process is a standard UNIX-type process with a separate address space.

**SIMD**
Single Instruction Multiple Data. Processing in which a single instruction operates on multiple data elements that make up a vector data-type. Also known as vector processing. This style of programming implements data-level parallelism.

**SPMD**
Single Program Multiple Data. A common style of parallel computing. All processes use the same program, but each has its own data.

**SPE**
Synergistic Processor Element. Extends the PowerPC 64 architecture by acting as cooperative offload processors (synergistic processors), with the direct memory access (DMA) and synchronization mechanisms to communicate with them (memory flow control), and with enhancements for real-time management. There are 8 SPEs on each Cell/B.E. processor.

**SPU**
Synergistic Processor Unit. The part of an SPE that executes instructions from its local store (LS).

**System X**
This is a project-neutral description of the supervising system for a node.

**thread**
A sequence of instructions executed within the global context (shared memory space and other global resources) of a process that has created (spawned) the thread. Multiple threads (including multiple instances of the same sequence of instructions) can run simultaneously if each thread has its own architectural state (registers, program counter, flags, and other program-visible state). Each SPE can support only a single thread at any one time. Multiple SPEs can simultaneously support multiple threads. The PPE supports two threads at any one time, without the need for software to create the threads. It does this by duplicating the architectural state. A thread is typically created by the pthreads library.

**topology**
A topology is a configuration of DaCS elements in a system. The topology specifies how the different processing elements in a system are related to each other. DaCS assumes a tree topology: each DE has at most one parent.

**Work block**
A basic unit of data to be managed by the framework. It consists of one piece of the partitioned data, the corresponding output buffer, and related parameters. A work block is associated with a task. A task can have as many work blocks as necessary.

**Work queue**
An internal data structure of the accelerated library framework that holds the lists of work blocks to be processed by the active instances of the compute task.
