

A Trainable Model of Saliency-based Visual Attention

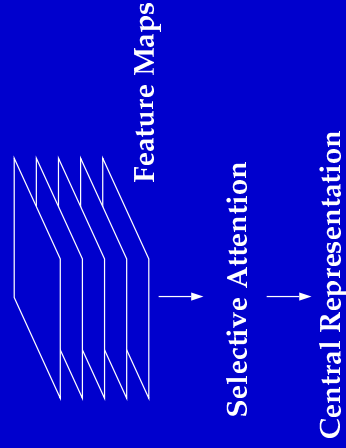

L. Itti, E. Niebur, J. Braun and C. Koch
 California Institute of Technology and
 Johns Hopkins University

Extraction of Visual Features

Overview

Model Architecture

- Extraction of early visual features
- saliency map
- dynamical attention shifting

Dynamical control of Attention

Combination of Features

Supervised learning of feature map weights:

$$w \leftarrow w + \eta (\text{max. inside target} - \text{average max. outside})$$

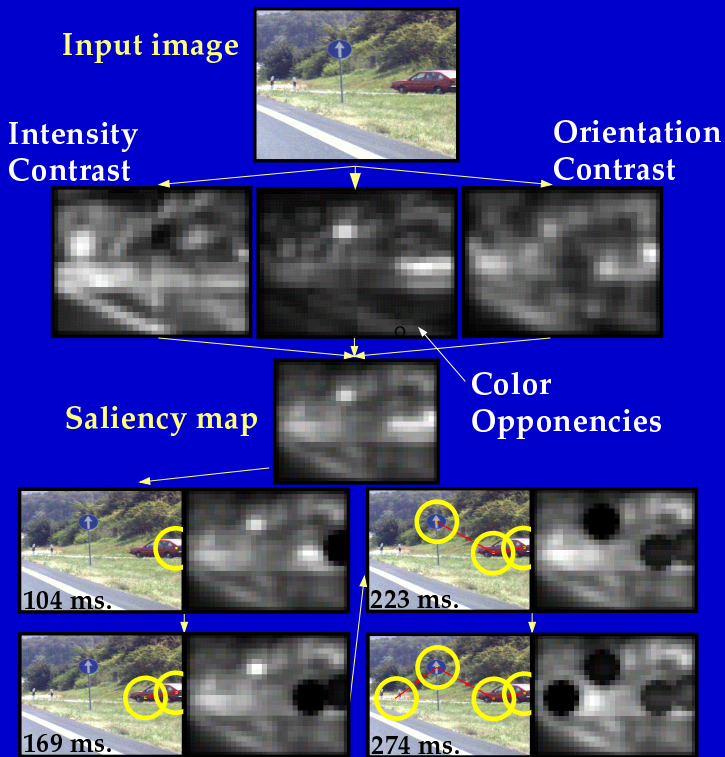

Naive linear model

Trained linear model (n=32)

Model Architecture

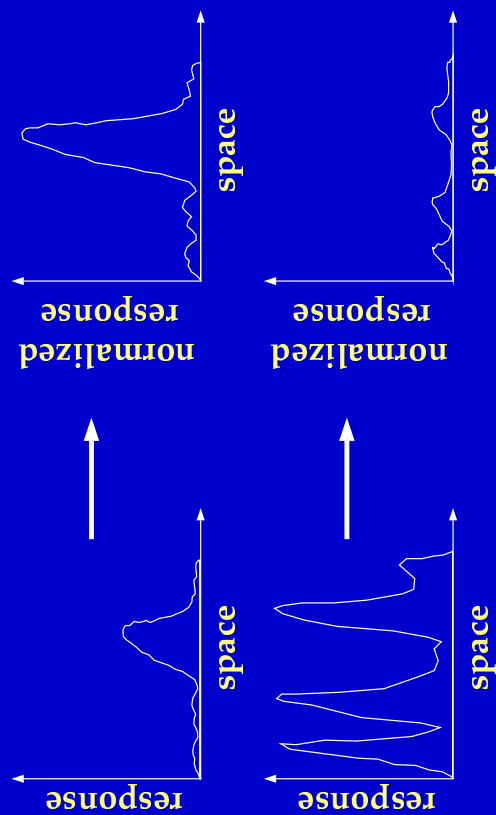

Combination of Features

Summation

Combination of features

Combination of Features

Contents-based non-linear combination:
 Map weight = (global max. - average local max.)²

Natural Images

Simulated Psychophysics

Conclusion

Architecture of early primate visual system

Adaptive non-linear feature combination
 yields best results

"Saliency map" approach works remarkably well
 on artificial and natural images
